Nephritic *Stone*, a foft, brittle, opaque ftone, not fufceptible of a good polifh; fmooth, and, as it were, unctuous to the touch; variegated with feveral colours, of which green is the principal. It is found in Saxony, Bohemia, Switzerland, Spain, and Mexico; and from the imaginary virtues afcribed to it in nephritic diforders, has been ranked among the precious ftones, but differs exceedingly from them in all its fenfible qualities. Neumann finds fault with fome authors for referring this ftone to the jafpers, agates, or marbles; from all of which, he fays, it widely differs: it wants the red fpecks of the jafpers, the hardnefs and compactnefs of the others, and all of them want its unctuofity or foapinefs. Out of 60 grains of nephritic ftone, vinegar diffolved three; oil of vitriol feven; fpirit of vitriol 14; fpirit of nitre 16; aqua regia 18; and fpirit of falt 20. The fpirit of falt acquired a greenifh-yellow tincture; aqua regia a gold yellow; oil of vitriol a dark-brownifh; the other acids remained colourlefs. Both the marine acid and aqua regia left the undiffolved earth whitifh; the nitrous acid greyifh; the diluted vitriolic acid brownifh-yellow; the concentrated light reddifh-brown; the acetous,

tous, unchanged. An ounce of this fubftance powdered, and diftilled in a retort in an open fire, yielded about a drachm and an half of phlegm, which had a penetrating empyreumatic fmell, but made no change in the colour of the fyrup of violets. On diftilling four ounces together, there was an appearance of an actual empyreumatic oil, with a faline matter, which was found to be fal ammoniac. The matter remaining in the retort was of a reddifh-brown colour. An ounce of the powdered ftone, mixed with an equal quantity of fixed alkaline falt, and urged with a ftrong fire, did not melt, but formed a quite porous mafs, in colour inclining to reddifh-grey, and weighing two drachms lefs than the mixture did at firft. Dr Lewis tells us, that the nephritic ftone is a fpecies of the indurated clays, called, from their unctuofity, *fteatitæ*. With thefe it agrees, not only in its obvious properties, but likewife in its burning hard, the peculiar characteriftic of argillaceous earths. Its green colour feems to proceed from copper. Pott relates, that on fufion with an equal quantity of borax, it yielded a beautiful red mafs refembling an agate, with a grain of copper at the bottom. The nephritic ftone is confiderably the hardeft of all the fubftances of this clafs.

NEPHRITICS, in pharmacy, medicines proper for difeafes of the kidneys, efpecially the ftone.—Such particularly are the roots of althæa, dog's-grafs, afparagus, fago, pellitory of the wall, mallows, pimpinella, red chick-peafe, peach-kernels, turpentine, &c.

NEPHRITIS, or inflammation of the kidneys. See MEDICINE, n° 304.

NEPOS (Cornelius), a celebrated Latin hiftorian, born at Hoftilia near Verona, flourifhed in the time of the emperor Auguftus. He was the friend of Cicero and Atticus; and compofed feveral excellent works, of which there are only extant the lives of the moft illuftrious Greek and Roman captains.

NEPTUNE, in Pagan worfhip, the god of the fea, was the fon of Saturn and Vefta, or Ops, and the brother of Jupiter and Pluto. He affifted Jupiter in his expeditions; on which that god, when he arrived at the fupreme power, affigned him the fea and the iflands for his empire. He was, however, expelled from heaven with Apollo, for confpiring againft Jupiter, when they were both employed by Laomedon king of Phrygia in building the walls of Troy; but that prince difmiffing Neptune without a reward, he fent a fea-monfter to lay wafte the country, on which he was obliged to expofe his daughter Hefione. He is faid to have been the firft inventor of horfemanfhip and chariot-racing; on which account Mithridates king of Pontus threw chariots drawn by four horfes into the fea in honour of this god; and the Romans inftituted horfe-races in the circus at his feftival, during which all other horfes left working, and the mules were adorned with wreaths of flowers.

In a conteft with Minerva he produced a horfe by ftriking the earth with his trident; and on another occafion, in a trial of fkill with Minerva and Vulcan, produced a bull, whence that animal was facrificed to him. His favourite wife was Amphytrite, whom he long courted in vain, till fending the dolphin to intercede for him, he met with fuccefs; on which he rewarded the dolphin by placing him among the ftars. He had alfo two other wives, one of whom was called *Salafia*, from the falt water; the other *Venilia*, from the ebbing and flowing of the tides. He had likewife many concubines, by whom he had a great number of children. He is reprefented with black hair, with a garment of an azure or fea-green, holding his trident in his hand, and feated in a large fhell drawn by fea-horfes, attended by the fea-gods Palemon, Glaucus, and Phorcys, and the fea goddeffes Thetis, Melita, and Panopæa, and a long train of tritons and fea-nymphs.

NEREIDS, in the Pagan theology, fea-nymphs, daughters of Nereus and Doris.—The Nereids were efteemed very handfome; infomuch that Caffiope, the wife of Cepheus king of Ethiopia, having triumphed over all the beauties of the age, and daring to vie with the Nereids, they were fo enraged that they fent a prodigious fea-monfter into the country; and, to appeafe them, fhe was commanded by the oracle to expofe her daughter Andromeda, bound to a rock, to be devoured by the monfter. In ancient monuments, the Nereids are reprefented riding upon fea-horfes; fometimes with an entire human form, and at other times with the tail of a fifh.

NEREIS, in zoology, a genus of animals belonging to the order of vermes mollufca. The body is oblong, linear, and fitted for creeping; it is furnifhed with lateral pencilled tentacula. There are 11 fpecies; of which the moft remarkable is the noctiluca, being one of the caufes of the luminoufnefs of the fea. They are inhabitants of almoft every fea; and illuminate the water like glow-worms, but with a brighter fplendour, fo as at night to make the element appear as if on fire all around. Their bodies are fo minute as to elude examination by the naked eye.

NEREUS, in fabulous hiftory, a marine deity, was the fon of Oceanus and Thetis. He fettled in the Ægean Sea, was confidered as a prophet, and had the power of affuming what form he pleafed. He married his fifter Doris, by whom he had 50 daughters called the *Nereids*, who conftantly attended on Neptune, and when he went abroad furrounded his chariot.

NERO (Domitius) emperor, fon of Caius Domitius Ænobarbus, and of Agrippina, who married Claudius, whom Nero fucceeded, A. D. 54, aged 18. He protefted he would follow the example of Auguftus, and at firft he did; and as they once prefented him the fentence of a perfon condemned to death, "I wifh," faid he, "that I could not write." But after five years reign he fell into the moft extravagant crimes that ever entered the imagination of man. He would appear upon the ftage in wonan's drefs. He commited fodomy with the greateft debauchees, and particularly Sporus, whom he kept in quality of his wife, and caufed to be dreffed like a woman; which gave occafion to that pleafant faying, "That the world had been happy if his father Domitius had had fuch a wife." He caufed his mother to be murdered, his wife to be put to death, and his mafter Seneca to lofe his life, &c. and wifhed that mankind had but one head, that he might have the pleafure of cutting it off. To have the glory of rebuilding Rome, he fet it on fire, laid the blame upon the Chriftians, and began the firft perfecution againft them.

them. Being exhausted by his immense profusion, and become the common detestation of mankind, his armies in Gaul declared against him, and Galba revolted in Spain. This cast him into despair, and in a rage he cried out, "Have I neither friend nor enemy?" So he was forced to turn his own executioner, A. D. 68, in the 32d year of his age and 14th of his reign.

NERVA (Cocceius), emperor after Domitian. He recalled those who had been banished for their religion, and forgot nothing that might contribute to the restoring of the empire to its former lustre; but finding his age would not suffer him to finish it, he adopted Trajan, and died A. C. 98.

NERVES, in anatomy; certain white glistening cords, proceeding from the brain and spinal marrow, and dividing into very small branches, which are sent off throughout all parts of the body; and which are found to be the organs of sensation and motion. See ANATOMY, n° 400.

NERVOUS FLUID. See ANATOMY, n° 400, l.

NEST. See NIDUS.

Eatable Birds-NESTS. See BIRDS-*Nests*.

NESTOR, in fabulous history, king of Pylos, and the son of Neleus and Chloris. He subdued the Eleans, and conquered the Centaurs, who would have carried off Hippodamia. He afterwards went to the siege of Troy with Agamemnon, who had a particular esteem for him on account of his wisdom and eloquence. He was then, according to Homer, so old, that he had seen three generations of men.

NESTORIANS, a Christian sect, the followers of Nestorius bishop and patriarch of Constantinople; who, about the year 520, taught that there were two persons in Jesus Christ, the divine and the human, which are united not hypostatically or substantially, but in a mystical manner; whence he concluded, that Mary was the mother of Christ, and not the mother of God. For this opinion Nestorius was condemned and deposed by the council of Ephesus; and the decree of this council was confirmed by the emperor Theodosius, who banished the bishop to a monastery.

NET, a device for catching fish and fowl. See the article FISHERY.

The taking fowls by nets is the readiest and most advantageous of all others, where numbers are to be taken. The making the nets is very easy, and what every true sportsman ought to be able to do for himself. All the necessary tools are wooden needles, of which there should be several of different sizes, some round and others flat; a pair of round-pointed and flat scissars; and a wheel to wind off the thread. The packthread is to be of different strength and thickness, according to the sort of birds to be taken; and the general size of the meshes, if not for very small birds, is two inches from point to point. The nets should neither be made too deep nor too long, for they are then difficult to manage; and they must be verged on each side with twisted thread. The natural colour of the thread is too bright and pale, and is therefore in many cases to be altered. The most usual colour is the russet; which is to be obtained by plunging the net, after it is made, into a tanner's pit, and letting it lie there till it be sufficiently tinged: this is of a double service to the net, since it preserves the thread as well as alters the colour. The green colour is given by chopping some green wheat and boiling it in water, and then soaking the net in this green tincture. The yellow colour is given in the same manner with the decoction of celandine; which gives a pale straw-colour, which is the colour of stubble in the harvest-time. The brown nets are to be used on ploughed lands, the green on grass-grounds, and the yellow on stubble-lands.

NET, *Neat*, in commerce, something pure, and unadulterated with any foreign mixture.

Thus, wine is said to be *net* when not falsified or balderdashed; and coffee, rice, pepper, &c. are *net* when the filth and ordures are separated from them. See NEAT.

A diamond is said to be *net* when it has no stains or flaws; a crystal, when transparent throughout.

NET is also used for what remains after the tare has been taken out of the weight of any merchandise; *i. e.* when it is weighed clear of all package. See TARE.

Thus we say, a barrel of cochineal weighs 450 pounds; the tare is 50 pounds, and there remains *net* 400 pounds.

NET *Produce*, a term used to express what any commodity has yielded, all tare and charges deducted.

The merchants sometimes use the Italian words *netto proceduto*, for net produce.

NETHERLANDS, anciently called *Belgia*, but since denominated *Low Countries* or *Netherlands*, from their low situation, are situated between 2° and 7° of east longitude, and between 50° and 53° 30′ of north latitude: and are bounded by the German sea on the north, Germany on the east, by Lorrain and France on the south, and by another part of France and the British seas on the west; extending near 300 miles in length from north to south, and 200 miles in breadth from east to west. They consist of 17 provinces; 10 of which are called the *Austrian and French Netherlands*, and the other seven the *United Provinces*.

The *Austrian Netherlands* consist of the greatest part of the duchies of Brabant, Limburg, and Luxemburg, with a part of that of Gueldres; and of the counties of Flanders, Hennegau, and Namur. The Netherlands formerly made a part of the circle of Burgundy, the whole of which once belonged to the house of Austria, and on the death of Charles V. devolved to the Burgundian Spanish line of that house; but was all afterwards lost, except the abovementioned countries, which, on the death of Charles II. king of Spain, fell to the German line of the Austrian family. These Austrian Netherlands are still considered as a circle of the empire, of which the archducal house, as being sovereign of the whole, is the sole director and summoning prince. This circle contributes its share to the imposts of the empire, and sends an envoy to the diet; but is not subject to the judicatories of the empire. It is wholly Catholic, and under a governor-general appointed by the court of Vienna.

The *French Netherlands* consist of a part of the duchy of Luxemburg, of the province of Hainault, of the earldom of Flanders, the bishopric of Liege, the Cambresis, and the county of Namur; and this government, the greatest part of which belongs to the parliament of Douay, comprehends French Flanders,

the

the Cambrefis, French Hainault, and the French part of the earldom of Namur.—French Flanders abounds in grain, vegetables, flax, and cattle, but is in want of wood.

For the *Dutch Netherlands*, fee UNITED *Provinces*.

NETSCHER (Gafpard), an eminent painter, born at Prague in Bohemia in 1639. His father dying while he was an engineer in the Polifh fervice, his mother was obliged, on account of her religion, fuddenly to leave Prague with her three fons. When fhe had proceeded three leagues, fhe ftopped at a caftle; which being foon after befieged, two of her fons were ftarved to death; but fhe herfelf found means to efcape out of the fortrefs by night, and to fave her only remaining child. Carrying him in her arms, fhe reached Arnheim in Guelderland, where fhe found means to fupport herfelf, and breed up her fon. At length a doctor of phyfic took young Netfcher into his patronage, with the view of giving him an education proper for a phyfician: but Netfcher's genius leading him to painting, he could not forbear fcrawling out defigns upon the paper on which he wrote his themes; and it being found impoffible to conquer his fondnefs for drawing, he was fent to a glazier, who was the only perfon in the town that underftood drawing. Netfcher foon finding himfelf above receiving any farther affiftance from his mafter, was fent to Deventer, to a painter named *Terburg*, who was an able artift and burgomafter of the town; and having acquired under him a great command of his pencil, went to Holland, where he worked a long time for the dealers in pictures, who paid him very little for his pieces, which they fold at a high price. Difgufted at this ungenerous treatment, he refolved to go to Rome, and for that purpofe embarked on board a veffel bound for Bourdeaux. But his marrying in that city prevented his travelling into Italy: and therefore, returning into Holland, he fettled at the Hague; where obferving that portait-painting was the moft profitable, he applied himfelf folely to it, and acquired fuch reputation, that there is not a confiderable family in Holland that has not fome of his portraits; and befides, the greateft part of the foreign minifters could not think of quitting Holland without carrying with them one of Netfcher's portraits, whence they are to be feen all over Europe. He died at the Hague, in 1684; leaving two fons, Theodore and Conftantine Netfcher, both of them good portrait-painters.

NETTINGS, in a fhip, a fort of grates made of fmall ropes feized together with rope-yarn or twine, and fixed on the quarters and in the tops; they are fometimes ftretched upon the ledges from the wafte-trees to the roof-trees, from the top of the forecaftle to the poop, and fometimes are laid in the wafte of a fhip to ferve inftead of gratings.

NETTLE, in botany. See URTICA.

Sea-NETTLE. See MEDUSA, and ANIMAL-*Flower*.

NETTLE-*Tree*. See CELTIS.

NETTUNO, a handfome town of Italy, in the Campagnia of Rome. It is but thinly peopled, though feated in a fertile foil. The inhabitants are almoft all hunters. E. Long. 12. 57. N. Lat. 41. 30.

NEWBURG, the name of feveral towns of Germany, two of which are the chief towns of duchies of the fame name; one in Bavaria, and the other in the Palatinate.

NEVERS, a confiderable town of France, and capital of Nivernois, in Orleanois, with the title of a duchy, an ancient caftle, and a bifhop's fee. It is built in the form of an amphitheatre, and contains feveral fine buildings. It is feated on the river Loir, over which there is an handfome bridge, and at the end of it a fine large caufeway reaching to the town. E. Long. 3. 14. N. Lat. 46. 59.

NEUFCHATTEAU, a town of France, in Lorrain, and capital of the chatellenie of Chatenoi. It is an handfome, populous, trading town; having an abbey of the nuns of St Clair, a commandery of Malta, and feveral convents of monks and nuns. It is feated in a bottom, in a foil fertile in corn, wine, and all the neceffaries of life, on the river Mouzon. E. Long. 5. 45. N. Lat. 48. 20.

NEUFCHATTEL, a fovereign county of Swifferland, bounded on the weft by the Franche Comte, on the north by the bifhopric of Bafle, and on the eaft and fouth by the cantons of Berne and Friburg; it is about 40 miles in length, and 20 in breadth. It had its own counts for a long time; the laft of whom dying in 1694 without iffue, it came to Mary of Orleans, duchefs of Nemours, his only fifter, who died without iffue in 1703: there were then 13 competitors; but, at an affembly of the ftates in 1707, they unanimoufly chofe the king of Pruffia for their fovereign, who has placed a governor therein. It is well peopled; and contains three cities, one town, 90 villages, and about 300 houfes difperfed in the mountains. The inhabitants are all Proteftants, except two Roman Catholic villages; and in 1529 they entered into a ftrict alliance with the cantons of Berne, Friburg, Soleure, and Lucern. The air is healthy and temperate, but the foil not every where equally fertile; however, there are large vineyards, which produce white and red wine, which laft is excellent. The paftures on the mountains feed a great number of all forts of cattle; and there are plenty of deer in the forefts; befides large trouts, and other good fifh, in the lakes and rivers. The people are ingenious, polite, active, induftrious, and laborious.

NEUFCHATTEL, an handfome town of Swifferland, capital of a county of the fame name. There are feveral ancient ruins near it, which fhew its former extent; and there are two large churches, befides a caftle where the governor refides. It is feated on a lake of the fame name, 17 miles in length and five in breadth, and the fide of the harbour is the ufual walk of the inhabitants. It has a grand and little council: the firft is compofed of 40 perfons, with two mafters of the keys; the little council confifts of 24 members, comprehending the mayor, who is prefident. Thefe two councils affemble regularly every month. The ecclefiaftics likewife affemble every month, to confult on affairs belonging to the church, and to fill up the places of minifters that die. They choofe a dean every year, who is prefident of the general affemblies, which are called *claffes*; and fometimes he is confirmed in this dignity. E. Long. 7. 10. N. Lat. 47. 5.

NEVIS, one of the Caribbee iflands, lying about feven leagues north of Montferrat, and feparated from St Chriftopher's by a narrow channel. It makes a beautiful appearance from the fea, being a large conical

cal mountain covered with fine trees, of an eafy afcent on every fide, and entirely cultivated. The circumference is about 21 miles, with a confiderable tract of level ground all around. The climate in the lower part is reckoned to be warmer than Barbadoes, but it is more temperate towards the fummit. The foil is very fine in the lower part, but grows coarfer as we afcend. The productions are nearly the fame with thofe of St Chriftopher. There are three pretty good roads or bays, with fmall towns in their vicinity; Charles-town, Moreton-Bay, and Newcaftle. This pleafant ifland was fettled under the aufpices of Sir Thomas Warner from St Chriftopher's. His fucceffor, governor Lake, was confidered as the Solon of this little country, in which he difpofed of every thing with fuch prudence, wifdom, and juftice, as procured him an high reputation with the French as well as Englifh. In the Dutch war they met with fome difturbance from the French; but by being covered by an Englifh fquadron, the enemy were obliged to defift from their intended invafion, after a fmart engagement in fight of the ifland. Sir William Stapleton fometimes refided here, and Sir Nathaniel Johnfon conftantly, at which time the inhabitants of Nevis were computed at 30,000. In the war immediately after the revolution, they exerted themfelves gallantly, and had two regiments of 300 men each. In that of queen Anne they behaved equally well, tho' they were lefs fortunate; for the French landing with a fuperior force, and having inveigled moft of their flaves, they were forced to capitulate. About 4000 of thefe flaves the French carried away and fold to the Spaniards, to work in their mines. The parliament, after making due inquiry into the loffes they had fuftained, voted them about a third part of the fum in which they had fuffered. Thefe loffes by war, an epidemic difeafe, and repeated hurricanes, exceedingly diminifhed the number of the people. They are now thought not to exceed 2000 or 3000 whites, and 6000 blacks. There is here a lieutenant-governor, with a council, and an affembly, which is compofed of three members from each of the five parifhes into which the ifland is divided. The commodities are cotton and fugar; and about 20 fail of fhips are annually employed in this trade.

NEURITICS, in pharmacy, medicines good in diforders of the nerves.

NEUROGRAPHY, fignifies a defcription of the nerves. See ANATOMY, n° 400.

NEUROPTERA. See ZOOLOGY.

NEUTER, a perfon indifferent, who has efpoufed neither party, and is neither friend nor foe.

A judge ought to be neuter in the caufes he judges; in queftions, where reafon appears neuter, a man fhould ever incline to the fide of the unhappy.

NEUTER, in grammar, denotes a fort of gender of nouns, which are neither mafculine nor feminine. See GENDER.

The Latins have three kinds of genders, mafculine, feminine, and neuter. In Englifh, and other modern tongues, there is no fuch thing as neuter nouns. See NOUN.

Verbs NEUTER, by fome grammarians called *intranfitive verbs*, are thofe which govern nothing, and that are neither active nor pofitive. See VERB.

When the action expreffed by the verb has no object to fall upon, but the verb alone fupplies the whole idea of the action; the verb is faid to be *neuter*: as, I fleep, thou yawneft, he fneezes, we walk, ye run, they ftand ftill.

Some divide verbs neuter into, 1. Such as do not fignify any action, but a quality; as *albet*, "it is white;" or a fituation, as *fedet*, "he fits:" or have fome relation to place; as *adeft*, "he is prefent;" or to fome other ftate or attribute, as *regnat*, "he rules," &c. And, 2. Thofe that do fignify actions, though thofe fuch as do not pafs into any fubject different from the actor; as to dine, to fup, to play, &c.

But this latter kind fometimes ceafe to be *neuter*, and commence active; efpecially in Greek and Latin, when a fubject is given them: as, *vivere vitam*, *ambulare viam*, *pugnare pugnam*. Thus the old French poets fay, *Soupirer fon tourment*; the Englifh, to *figh his woes*, &c.

But this is obferved only to obtain where fomething particular is to be expreffed, not contained, in the verb: as, *vivere vitam beatam*, to live a happy life; *pugnare bonam pugnam*, to fight a good fight, &c.

According to the abbot de Dangeau, *verbs neuter* may be divided into *active* and *paffive*; the firft, thofe that form their tenfes in Englifh, by the auxiliary verb *to have*; in French, by *avoir*. The fecond, thofe that form them in Englifh with the verb *to be*; in French *etre*.—Thus, to fleep, to yawn, *dormir* and *eternuer*, are *neuters active*.—To come, and to arrive, are *neuters paffive*.

NEUTRAL *Salts*, among chemifts, thofe compounded of an acid with any other fubftance capable of uniting with it and deftroying its acidity. Thofe in which the acid is faturated with an earth or a metal are called *imperfect*, but thofe in which a pure alkali is employed are called *perfect*, neutrals.

NEUTRALITY, the ftate of a perfon or thing that is neuter, or that takes part with neither fide.

NEWCASTLE, the capital of the county of Northumberland in England, a large, populous, and flourifhing town, fituated on the north bank of the river Tyne, about 300 miles to the northward of London. It is connected, by means of a bridge with the fuburbs of Gatefhead, which, being on the fouthern fide of the river, is part of the bifhopric of Durham. Near the fpot where the town now ftands, there was of old a fort called *Moncafter*; and Robert, fon of William the Conqueror, having built another to overawe the Scots, beftowed upon it the name of *Newcaftle*, in contradiftinction to the old fortrefs. Divers monafteries and hofpitals being raifed around it, the place, in a little time, fwelled into a town; and the walls of it were begun in the reign of Edward I. by a rich burgher, who had been taken by the Scots, and paid a large ranfom for his liberty. It is at prefent furrounded by a ftrong wall, in which there are feven gates and as many turrets, with fome cafemates faid to be bomb-proof. It was created a borough by king Richard II. who granted permiffion to carry a fword before the mayor; and king Henry VI. erected it into a town and county incorporate, independent of Northumberland. The magiftracy confifts of a mayor, 19 aldermen, a fheriff, a recorder, a town-clerk, a clerk of the chambers, two coroners, eight chamberlains, a fword-bearer, with a

cap of maintenance, a water-bailiff with a great mace, and feven ferjeants at mace. Newcaftle has been expofed to frequent incurfions and fieges of the Scots, before the union of the two crowns; and in the great rebellion, the army of that kingdom, under the command of Leflie, took it by ftorm: but it has long ago retrieved all its loffes, and become the great emporium of the north of England for coal and other merchandize. The town is built upon the declivity of a hill, which renders the ftreets fteep and incommodious. The houfes are crowded together fo as to exhibit but a difagreeable appearance: yet one or two of the ftreets are large, fpacious, and well paved. The town is overlooked by the old ruinous caftle: the exchange and cuftom-houfe are magnificent buildings, but too clofe to the river; along the bank of which there is a fine key or wharf faced with freeftone, to which fhips of ordinary burden can carry their broadfides to be loaded or unloaded. But the coal-fhips are loaded at or near Shields, feven miles farther down the river; their lading being conveyed thither in lighters, which they call *keels*. The number of the keelmen who work in thefe lighters, exceed 6000, who live in a fuburb called *Sandgate*. They have, by a contribution among themfelves, built a noble hofpital for fuch of their poor brethren as are difabled by accident, or fuperannuated and paft labour. The principal church of Newcaftle, called *St Nicholas*, is a ftately old fabric, built by David king of Scotland, with a fine fteeple of rare architecture: here are, befides, fix churches or chapels. We may number among the public edifices, an elegant manfion-houfe for the mayor; a noble hall for the furgeons, with a mufeum; a ftately infirmary on the model of that at Edinburgh; a library belonging to the corporation; a large prifon called *Newgate;* feveral meeting-houfes, and charity-fchools well endowed. The number of inhabitants amounts to above 40,000; and many of them are wealthy, and live with fplendour. They are generally bold, rough, and induftrious; enriching themfelves with the coal-trade, and other branches of commerce and manufacture, fuch as fhip-building, glafs-making, falt-works, and hard-ware or wrought iron. The place is particularly famous for grind-ftones, which are exported to all the countries in Europe. The fafhionable people live in the upper part of the town, at a diftance from the river, where they poffefs elegant houfes and gardens, and enjoy themfelves at comedies, affemblies, and other polite diverfions. The houfes are chiefly built of ftone, fome are of brick, and a very few of timber. The revenue of the town, amounting to 8000 l. a-year, is confiderably larger than that of any other corporation-borough in England: and from this the mayor is indulged with an annual allowance of 600 l. befides the maintenance of a coach, barge, and manfion-houfe.

NEWCASTLE (Duke of). See CAVENDISH.

NEWEL, in architecture, is the upright poft which a pair of winding ftairs turn about; this is properly a cylinder of ftone, which bears on the ground, and is formed by the end of the fteps of the winding ftairs.

NEWFIDLER-SEA, a lake in Hungary, 17 miles in length, and 6 in breadth.

NEWFOREST, a part of Hampfhire, lying on the Englifh channel, oppofite to the Ifle of Wight. It was made by William the Conqueror, who caufed 36 churches, and all the houfes belonging thereto, to be pulled down, that there might be no obftruction in hunting the game. It is now appropriated by act of parliament for the production of oaks, to be employed in building the royal navy.

NEWFOUNDLAND, a large ifland of North America, belonging to Great Britain, lying between 46. 50. and 51. 30. N. Lat. and between 53. 30. and 58. 20. W. Long. from London. The form is that of an irregular triangle, the bafe or fouth fide being 80 leagues in extent; the eaft fide is the longeft; and the whole circumference about 150 leagues. It is bounded on the north by the Straits of Belleifle, which feparate it from Labrador; on the eaft and fouth it hath the Atlantic Ocean, and on the weft the Gulph of St Laurence. The climate is rather fevere; and the foil, at leaft on the fea-coaft, which is all that we know of it, is poor and barren. A few kitchen vegetables with ftrawberries and rafberries are all its produce. The country within land is mountainous, and abounds with timber; there are feveral rivers which are plentifully ftored with various forts of fifh, abundance of deep bays, and many good ports. St John's and Placentia are the two principal fettlements, and at each of thefe there is a fort; the number of people who remain here in the winter hath been computed at 4000. The French, by the treaty of Utrecht, were permitted to fifh from Cape Bonavifta on the eaft fide round the north of the ifland to Point Rich on the weft; and by the treaty of Paris, they are allowed the ifles of St Pierre and Miquelon, upon which they are to dry their fifh, but not to erect fortifications of any kind.

The great importance of this place arifes from its fifhery, which is in part carried on by the inhabitants at the feveral harbours, which are about 20 in number, who take vaft quantities of cod near the coaft, which they bring in and cure at their leifure, in order to have it ready for the fhips when they arrive. But the great and extenfive fifhery is on the banks at fome diftance from the ifland. The great bank lies 20 leagues from the neareft point of land from the latitude of 41 to 49, ftretching 300 miles in length and 75 in breadth. To the eaft of this lies the Falfe Bank; the next is ftyled *Vert* or *the Green Bank*, about 240 miles long, and 120 over; then Banquero, about the fame fize; the fhoals of Sand Ifland, Whale Bank, and the Bank of St Peter's, with feveral others of lefs note, all abounding with fifh.

The cod are caught only by a hook, and an expert fifher will take from 150 to 300 and upwards in a day; for the fifh never bite in the night, and the labour is very great. The feafon is from May to October, in the height of which there are from 500 to 700 fail upon the banks at a time. The fifh caught in the fpring-months are beft; they are cured in very different ways. Some are ftyled *white fifh*, others *mud fifh*, which are ftowed and falted in the hold, and will not keep long; but the beft and moft valuable are the dried cod. The quantity taken is prodigious; yet in fome feafons and in different places varies confiderably, as the fifh frequently change their ftations. The *fifhing-fhips*, as they are called, lie upon the banks, with the help of their

Newfoundland ‖ Newton.

their boats take and cure their own fiſh, and as ſoon as they are full ſail for a market. The ſack-ſhips proceed directly to the iſland, where they purchaſe fiſh from the inhabitants either by barter or bills of exchange. The principal markets for cod are Spain, Portugal, Italy, and the Weſt Indies. The value of this fiſhery is computed at ſome hundred thouſand pounds anually; employing, beſides ſeveral hundred ſhips, ſome thouſands of ſeamen, and affording a maintenance to a number of tradeſmen of different occupations, by which many large towns on the weſt ſide of England accumulate much wealth, and at the ſame time contribute in many reſpects to the benefit of the public.

The great utility of this fiſhery was very early ſeen, and very vigorouſly purſued; for in the beginning of the reign of king James I. we had two hundred and fifty ſail employed therein. It is computed, that three quintals of wet fiſh make one quintal of dried cod. Beſides, the livers of every hundred quintals make a hogſhead of oil; and excluſive of theſe, there are many leſſer advantages that go in diminution of the expence. The fiſhery, as we have ſaid above, produces differently in different ſeaſons; but it is judged to be a very good one when it produces 300,000 quintals of fiſh, and 3000 barrels of oil, both equally saleable and valuable commodities. As every ſhip carries 12, and each of their boats eight men, and as theſe return home in ſix months, there cannot be a more noble nurſery for ſeamen. The artificers and traders employed in building, victualling, and repairing theſe veſſels, are very numerous in the reſpective ports from which they ſail. Theſe circumſtances juſtify the particular attention paid by government to this branch of the public ſervice; in reſpect to which, that they may be well informed, an annual and very diſtinct account, by which the whole is ſeen at one view, is delivered by the proper officer to the governor of Newfoundland, that is, to the commodore of his majeſty's ſquadron.

NEWMARKET, a town of England, partly in Cambridgeſhire, and partly in Suffolk. It conſiſts of one well-built ſtreet, ſeated on the great road, and full of inns. It is chiefly noted for its horſe-races. E. Long. 0. 25. N. Lat. 52. 16.

NEWT, or Eft, in zoology, the common lizard. See Lacerta.

NEWTON (Sir Iſaac), one of the greateſt philoſophers and mathematicians the world has produced, was the only child of Mr John Newton of Coleſworth, not far from Grantham in Lincolnſhire, who had an eſtate of about 120*l. per annum*, which he kept in his own hands. He was born at that place on Chriſtmas-day 1642. His father dying when he was young, his mother's brother, a clergyman of the name of *Ayſcough*, or *Aſkew*, who lived near her, and directed all her affairs after the death of Mr Newton, put her ſon to ſchool at Grantham. When he had finiſhed his ſchool-learning, his mother took him home; intending, as ſhe had no other child, to have the pleaſure of his company; and that he, as his father had done, ſhould occupy his own eſtate. But his uncle happening to find him in a hay-loft at Grantham, working a mathematical problem, and having otherwiſe obſerved the boy's mind to be uncommonly bent upon learning, he prevailed upon her to part with him; and ſhe ſent him

Newton.

to Trinity College in Cambridge, where her brother, having himſelf been a member of it, had ſtill many friends. Iſaac was ſoon taken notice of by Dr Iſaac Barrow; who, obſerving his bright genius, contracted a great friendſhip for him. M. De Fontenelle tells us, "That in learning mathematics he did not ſtudy Euclid, who ſeemed to him too plain and ſimple, and unworthy of taking up his time. He underſtood him almoſt before he read him, and a caſt of his eye upon the contents of his theorems was ſufficient to make him maſter of them. He advanced at once to the geometry of Des Cartes, Kepler's optics, &c. It is certain, that he had made his great diſcoveries in geometry, and laid the foundation of his two famous works the *Principia* and the *Optics*, by the time he was 24 years of age."

In 1664, he took the degree of bachelor of arts; and in 1668 that of maſter, being elected the year before fellow of his college. He had before this time diſcovered the method of fluxions; and in 1669, he was choſen profeſſor of mathematics in the univerſity of Cambridge, upon the reſignation of Dr Barrow. The ſame year, and the two following, he read a courſe of optical lectures in Latin, in the public ſchools of the univerſity; an Engliſh tranſlation of which was printed at London in 1728 in 8vo, as was the Latin original the next year in 4to. From the year 1671 to 1679, he held a correſpondence, by letters, with Mr Henry Oldenburg, ſecretary of the royal ſociety, and Mr John Collins, fellow of that ſociety; which letters contain a variety of curious obſervations.

Concerning the origin of his diſcoveries, we are told that as he ſat alone in a garden, the falling of ſome apples from a tree led him into a ſpeculation on the power of gravity; that as this power is not diminiſhed at the remoteſt diſtance from the centre of the earth to which we can riſe, it appeared to him reaſonable to conclude, that it muſt extend much farther than was uſually thought; and purſuing this ſpeculation by comparing the periods of the ſeveral planets with their diſtances from the ſun, he found, that if any power like gravity held them in their courſes, its ſtrength muſt decreaſe in the duplicate proportion of the increaſe of diſtance. This inquiry was dropped; but reſumed again, and gave riſe to his writing the treatiſe which he publiſhed in 1687 under the name of *Mathematical Principles of Natural Philoſophy*; a work looked upon as the production of a celeſtial intelligence rather than of a man. The very ſame year in which this great work was publiſhed, the univerſity of Cambridge was attacked by king James II. when he was one of its moſt zealous defenders, and was accordingly nominated one of the delegates of that univerſity to the high-commiſſion court; and the next year he was choſen one of their members for the convention-parliament, in which he ſat till it was diſſolved. In 1696, Mr Montague, then chancellor of the exchequer, and afterwards earl of Halifax, obtained for him of the king, the office of warden of the mint; in which employment he was of ſignal ſervice, when the money was called in to be recoined. Three years after, he was appointed maſter of the mint; a place of very conſiderable profit, which he held till his death. In 1699, he was elected one of the members of the royal aca-

Newton. demy of ſciences at Paris. In 1701, he was a ſecond time choſen member of parliament for the univerſity of Cambridge. In 1704, he publiſhed his *Optics;* which is a piece of philoſophy ſo new, that the ſcience may be conſidered as entirely owing to our author. In 1705, he was knighted by queen Anne. In 1707, he publiſhed his *Arithmetica Univerſalis*. In 1711, his *Analyſis per Quantitatum Series, Fluxiones et Differentias,* &c. was publiſhed by William Jones Eſq. In 1712, ſeveral letters of his were publiſhed in the *Commercium Epiſtolicum*. In the reign of George I. he was better known at court than before. The princeſs of Wales, afterwards qneen-conſort of England, uſed freqnently to propoſe queſtions to him, and to declare that ſhe thought herſelf happy to live at the ſame time with him, and have the pleaſure and advantage of his converſation. He had written a treatiſe of ancient chronology, which he did not think of publiſhing; but the princeſs deſired an abſtract, which ſhe would never part with. However, a copy of it ſtole abroad, and was carried into France; where it was tranſlated and printed, with ſome obſervations, which were afterwards anſwered by Sir Iſaac. But, in 1728, the Chronology itſelf was publiſhed at London in quarto; and was attacked by ſeveral perſons, and as zealouſly defended by Sir Iſaac's friends. The main deſign of it was to find out, from ſome tracts of the moſt ancient Greek aſtronomy, what was the poſition of the colures with reſpect to the fixed ſtars, in the time of Chiron the centaur. As it is now known that theſe ſtars have a motion in longitude of one degree in 72 years, if it is once known thro' what fixed ſtars the colure paſſed in Chiron's time, by taking the diſtance of theſe ſtars from thoſe through which it now paſſes, we might determine what number of years is elapſed ſince Chiron's time. As Chiron was one of the Argonants, this would fix the time of that famons expedition, and conſequently that of the Trojan war; the two great events upon which all the ancient chronology depends. Sir Iſaac places them 500 years nearer the birth of Chriſt than other chronologers generally do.

This great man had all along enjoyed a ſettled and equal ſtate of health to the age of 80, when he began to be afflicted with an incontinence of urine. However, for the five following years, he had great intervals of eaſe, which he procured by the obſervance of a ſtrict regimen. It was then believed that he certainly had the ſtone; and when the paroxyſms were ſo violent, that large drops of ſweat ran down his face, he never uttered the leaſt complaint, or expreſſed the ſmalleſt degree of impatience; but, as ſoon as he had a moment's eaſe, would ſmile and talk with his uſual cheerfulneſs. Till then he always read and wrote ſeveral hours in a day. He had the perfect uſe of all his ſenſes and underſtanding till the day before he died, which was on the 20th of March 1726-7, in the 85th year of his age.—He lay in ſtate in the Jeruſalem chamber at Weſtminſter, and on the 28th of March his body was conveyed into Weſtminſter abbey; the pall being ſupported by the lord chancellor, the dukes of Montroſe and Roxburgh, and the earls of Pembroke, Suſſex, and Macclesfield. The biſhop of Rocheſter read the funeral office, being attended by all the clergy of the church. The corps was interred juſt at the entrance into the choir, where a noble monument is erected to his memory. Newton.

Sir Iſaac was of a middling ſtature, and in the latter part of his life ſomewhat inclined to be fat. His countenance was pleaſing, and at the ſame time venerable. He never made uſe of ſpectacles, and loſt but one tooth during his whole life.

His temper is ſaid to have been ſo equal and mild, that no accident could diſturb it. Of this the following remarkable inſtance is related. Sir Iſaac had a favourite little dog, which he called *Diamond;* and being one day called out of his ſtudy into the next room, Diamond was left behind. When Sir Iſaac returned, having been abſent but a few minutes, he had the mortification to find, that Diamond having thrown down a lighted candle among ſome papers, the nearly finiſhed labour of many years was in flames, and almoſt conſumed to aſhes. This loſs, as Sir Iſaac was then very far advanced in years, was irretrievable; yet, without once ſtriking the dog, he only rebnked him with this exclamation, "Oh! Diamond! Diamond! thou little knoweſt the miſchief thou haſt done!"

He was a great lover of peace; and would rather have choſen to remain in obſcurity, than to have the calm of life ruffled by thoſe ſtorms and diſputes which genius and learning always draw upon thoſe that are too eminent for them. In contemplating his genius, it preſently becomes a doubt, which of theſe endowments had the greateſt ſhare, ſagacity, penetration, ſtrength, or diligence: and, after all, the mark that ſeems moſt to diſtinguiſh it is, that he himſelf made the juſteſt eſtimation of it, declaring, that, if he had done the world any ſervice, it was due to nothing but induſtry and patient thought; that he kept the ſubject under conſideration conſtantly before him, and waited till the firſt dawning opened gradually, by little and little, into a full and clear light. It is ſaid, that when he had any mathematical problems or ſolutions in his mind, he would never quit the ſubject on any account. Dinner has been often three hours ready for him before he could be brought to table: that his man often ſaid, when he has been getting up in a morning, he has ſometimes begun to dreſs, and with one leg in his breeches, ſat down again on the bed, where he has remained for hours before he got his cloaths on. From his love of peace, no doubt, aroſe that unuſual kind of horror which he had for all diſputes; a ſteady unbroken attention, free from thoſe frequent recoilings inſeparably incident to others, was his peculiar felicity; he knew it, and he knew the value of it. No wonder then that controverſy was looked on as his bane. When ſome objections, haſtily made to his diſcoveries concerning light and colours, induced him to lay aſide the deſign he had of publiſhing his optic lectures; we find him reflecting on that diſpute, into which he was unavoidably drawn thereby, in theſe terms: "I blamed my own imprudence for parting with ſo real a bleſſing as my quiet, to run after a ſhadow." It is true this ſhadow, as Mr Fontenelle obſerves, did not eſcape him afterwards, nor did it coſt him that quiet which he ſo much valued, but proved as much a real happineſs to him as his quiet itſelf; yet this was a happineſs of his own making: he took a reſolution, from theſe diſputes, not to publiſh any more about that theory, till he had put it above the reach of

of controverſy, by the exacteſt experiments, and the ſtricteſt demonſtrations; and accordingly it has never been called in queſtion ſince. In the ſame temper, after he had ſent the manuſcript of his *Principia* to the Royal Society, with his conſent to the printing of it by them; yet upon Mr Hooke's injuriouſly inſiſting that himſelf had demonſtrated Kepler's problem before our author, he determined, rather than be involved again in a controverſy, to ſuppreſs the third book, and was very hardly prevailed upon to alter that reſolution. It is true, the public was thereby a gainer; that book, which is indeed no more than a corollary of ſome propoſitions in the firſt, being originally drawn up in the popular way, with a deſign to publiſh it in that form; whereas he was now convinced that it would be beſt not to let it go abroad without a ſtrict demonſtration.

After all, notwithſtanding his anxious care to avoid every occaſion of breaking his intenſe application to ſtudy, he was at a great diſtance from being ſteeped in philoſophy: on the contrary, he could lay aſide his thoughts, though engaged in the moſt intricate reſearches, when his other affairs required his attendance; and, as ſoon as he had leiſure, reſume the ſubject at the point where he had left off. This he ſeems to have done not ſo much by any extraordinary ſtrength of memory, as by the force of his inventive faculty, to which every thing opened itſelf again with eaſe, if nothing intervened to ruffle him. The readineſs of his invention made him not think of putting his memory much to the trial; but this was the offspring of a vigorous intenſeneſs of though, out of which he was but a common man. He ſpent, therefore, the prime of his age in thoſe abſtruſe reſearches, when his ſituation in a college gave him leiſure, and even while ſtudy was his proper profeſſion. But, as ſoon as he was removed to the mint, he applied himſelf chiefly to the buſineſs of that office; and ſo far quitted mathematics and philoſophy, as not to engage in any purſuits of either kind afterwards.

The amiable quality of modeſty is repreſented as ſtanding foremoſt in the character of this great man's mind and manners. It was in reality greater than can be eaſily imagined, or will be readily believed: yet it always continued ſo without any alteration, though the whole world, ſays Fontenelle, conſpired againſt it; let us add, though he was thereby robbed of his invention of fluxions. Nicholas Mercator publiſhing his *Logarithmotechnia* in 1668, where he gave the quadrature of the hyperbola by an infinite ſeries, which was the firſt appearance in the learned world of a ſeries of this ſort drawn from the particular nature of the curve, and that in a manner very new and abſtracted; Dr Barrow, then at Cambridge, where Mr Newton, then about 26 years of age, reſided, recollected, that he had met with the ſame thing in the writings of that young gentleman; and there not confined to the hyperbola only, but extended, by general forms, to all ſorts of curves, even ſuch as are mechanical; to their quadratures, their rectifications, and their centres of gravity; to the ſolids formed by their relations, and to the ſuperficies of thoſe ſolids; ſo that, when their determinations were poſſible, the ſeries ſtopped at a certain point, or at leaſt their ſums were given by ſtated rules: and, if the abſolute determinations were impoſſible, they could yet be infinitely approximated; which is the happieſt and moſt refined method, ſays Mr Fontenelle, of ſupplying the defects of human knowledge that man's imagination could poſſibly invent. To be maſter of ſo fruitful and general a theory was a mine of gold to a geometrician; but it was a greater glory to have been the diſcoverer of ſo ſurpriſing and ingenious a ſyſtem. So that Mr Newton, finding by Mercator's book, that he was in the way to it, and that others might follow in his tract, ſhould naturally have been forward to open his treaſures, and ſecure the property, which conſiſted in making the diſcovery; but he contented himſelf with his treaſure which he had found, without regarding the glory. What an idea does it give us of his unparallelled modeſty, when we ſee him declaring, that he thought Mercator had intirely diſcovered his ſecret, or that others would, before he was of a proper age for writing? His MS. upon infinite ſeries was communicated to none but Mr John Collins and the Lord Brounker; and even that had not been complied with, but for Dr Barrow, who would not ſuffer him to indulge his modeſty ſo much as he deſired.

It is further obſerved, concerning this part of his character, that he never talked either of himſelf or others, nor ever behaved in ſuch a manner as to give the moſt malicious cenſurers the leaſt occaſion even to ſuſpect him of vanity. He was candid and affable, and always put himſelf upon a level with his company. He never thought either his merit or his reputation ſufficient to excuſe him from any of the common offices of ſocial life; no ſingularities, either natural or affected, diſtinguiſhed him from other men. Though he was firmly attached to the church of England, he was averſe to the perſecution of the non-conformiſts. He judged of men by their manners; and the true ſchiſmatics, in his opinion, were the vicious and the wicked. Not that he confined his principles to natural religion, for he was thoroughly perſuaded of the truth of revelation; and amidſt the great variety of books which he had conſtantly before him, that which he ſtudied with the greateſt application was the Bible: and he underſtood the nature and force of moral certainty as well as he did that of a ſtrict demonſtration.

Sir Iſaac did not neglect the opportunities of doing good, when the revenues of his patrimony, and a profitable employment, improved by a prudent œconomy, put it in his power. We have two remarkable inſtances of his bounty and generoſity; one to Mr M'Laurin, profeſſor of mathematics at Edinburgh, to whom he offered 20l. per annum; and the other to his niece Barton, who had an annuity of 100l. per annum ſettled upon her by him. When decency upon any occaſion required expence and ſhew, he was magnificent without grudging it, and with a very good grace; at all other times, that pomp which ſeems great to low minds only, was utterly retrenched, and the expence reſerved for better uſes. He never married, and perhaps he never had leiſure to think of it. Being immerſed in profound ſtudies during the prime of his age, and afterwards engaged in an employment of great importance, and even quite taken up with the company which his merit drew to him, he was not ſenſible of any vacancy in life, nor of the want of a companion at home. He left 32,000l. at his death; but made no will, which

Mr

Newtonian Philoſophy

Mr Fontenelle tells us was becauſe he thought a legacy was no gift. As to his works, beſides what were publiſhed in his life-time, there were found after his death, among his papers, ſeveral diſcourſes upon the ſubjects of antiquity, hiſtory, divinity, chemiſtry, and mathematics, ſeveral of which were publiſhed at different times.

NEWTONIAN *Philoſophy*, the doctrine of the univerſe, and particularly of the heavenly bodies, their laws, affections, &c. as delivered by Sir Iſaac Newton.

1 Different opinions concerning this philoſophy.

The term *Newtonian philoſophy* is applied very differently; whence divers confuſed notions relating thereto.—Some authors, under this philoſophy, include all the corpuſcular philoſophy, conſidered as it now ſtands corrected and reformed by the diſcoveries and improvements made in ſeveral parts thereof by Sir Iſaac Newton. In which ſenſe it is that Graveſande calls his elements of phyſics, *Introductio ad Philoſophiam Newtonianam*. And in this ſenſe the Newtonian is the ſame with the new philoſophy; and ſtands contradiſtinguiſhed from the Carteſian, the Peripatetic, and the ancient Corpuſcular.

Others, by *Newtonian philoſophy*, mean the method or order which Sir Iſaac Newton obſerves in philoſophiſing; *viz.* the reaſoning and drawing of concluſions directly from phænomena, excluſive of all previous hypotheſes; the beginning from ſimple principles; deducing the firſt powers and laws of nature from a few ſelect phenomena, and then applying thoſe laws, &c. to account for other things. And in this ſenſe the *Newtonian philoſophy* is the ſame with the *experimental philoſophy*, and ſtands oppoſed to the ancient *Corpuſcular*.

Others, by *Newtonian philoſophy*, mean that wherein phyſical bodies are conſidered mathematically, and where geometry and mechanics are applied to the ſolution of phænomena. In which ſenſe the Newtonian is the ſame with the *mechanical* and *mathematical philoſophy*.

Others again, by *Newtonian philoſophy*, underſtand that part of phyſical knowledge which Sir Iſaac Newton has handled, improved, and demonſtrated, in his *Principia*.

Others, laſtly, by *Newtonian philoſophy*, mean the new principles which Sir Iſaac Newton has brought into philoſophy; the new ſyſtem founded thereon; and the new ſolutions of phænomena thence deduced; or that which characterizes and diſtinguiſhes his philoſophy from all others.—Which is the ſenſe wherein we ſhall chiefly conſider it.

As to the hiſtory of this philoſophy, we have nothing to add to what has been given in the preceding article. It was firſt made public in the year 1687, by the author, then a fellow of Trinity-college, Cambridge; and in the year 1713, republiſhed with conſiderable improvements.—Several authors have ſince attempted to make it plainer; by ſetting aſide many of the more ſublime mathematical reſearches, and ſubſtituting either more obvious reaſonings or experiments in lieu thereof; particularly Whiſton in his *Prælect. Phyſ. Mathemat.* Graveſande in *Element. & Inſtit.* and Dr Pemberton in his *View*.

The whole of the *Newtonian philoſophy*, as delivered by the author, is contained in his *Principia*, or *Mathematical Principles of Natural Philoſophy*. He founds his ſyſtem on the following definitions.

2 Definitions on which the philoſophy is founded.

1. The quantity of matter is the meaſure of the ſame, ariſing from its denſity and bulk conjunctly.—Thus air of a double denſity, in a double ſpace, is quadruple in quantity; in a triple ſpace, ſextuple in quantity, &c.

2. The quantity of motion is the meaſure of the ſame, ariſing from the velocity and quantity of matter conjunctly. This is evident, becauſe the motion of the whole is the motion of all its parts; and therefore in a body double in quantity, with equal velocity, the motion is double, &c.

3 *Vis inſita* defined and objected to.

3. The *vis inſita*, or innate force of matter, is a power of reſiſting, by which every body, as much as in it lies, endeavours to perſevere in its preſent ſtate, whether it be of reſt, or moving uniformly forward in a right line.—This definition is proved to be juſt, only by the difficulty we find in moving any thing out of its place; and this difficulty is by ſome reckoned to proceed only from gravity. They contend, that in thoſe caſes where we can prevent the force of gravity from acting upon bodies, this power of reſiſtance becomes inſenſible, and the greateſt quantities of matter may be put in motion by the very leaſt force. Thus there have been balances formed ſo exact, that when loaded with 200 weight in each ſcale, they would turn by the addition of a ſingle drachm. In this caſe 400 lb. of matter was put in motion by a ſingle drachm, *i. e.* by $\frac{1}{51200}$ parts of its own quantity: and even this ſmall weight, they ſay, is only neceſſary on account of the inaccuracy of the machine; ſo that we have no reaſon to ſuppoſe, that, if the friction could be entirely removed, it would take more force to move a tun weight than a grain of ſand. This objection, however, is not taken notice of by Sir Iſaac; and he beſtows on the reſiſting power abovementioned, the name of *vis inertiæ*.

4. An impreſſed force is an action exerted upon a body, in order to change its ſtate, either of reſt, or of moving uniformly forward in a right line.—This force conſiſts in the action only; and remains no longer in the body when the action is over. For a body maintains every new ſtate it acquires by its *vis inertiæ* only.

5. A centripetal force is that by which bodies are drawn, impelled, or any way tend towards a point, as to a centre.—The quantity of any centripetal force may be conſidered as of three kinds, abſolute, accelerative, and motive.

6. The abſolute quantity of a centrifugal force is the meaſure of the ſame, proportional to the efficacy of the cauſe that propagates it from the centre, through the ſpaces round about.

7. The accelerative quantity of a centripetal force is the meaſure of the ſame, proportional to the velocity which it generates in a given time.

8. The motive quantity of a centripetal force is a meaſure of the ſame, proportional to the motion which it generates in a given time.—This is always known by the quantity of a force equal and contrary to it, that is juſt ſufficient to hinder the deſcent of the body.

SCHOLIA.

4 Of time.

I. Abſolute, true, and mathematical time, of itſelf, and from its own nature, flows equably, without regard

gard to any thing external, and, by another name, is called *duration*. Relative, apparent, and common time, is some sensible and external measure of duration, whether accurate or not, which is commonly used instead of true time; such as an hour, a day, a month, a year, &c.

5 Space. II. Absolute space, in its own nature, without regard to any thing external, remains always similar and immoveable. Relative space is some moveable dimension or measure of the absolute spaces; and which is vulgarly taken for immoveable space. Such is the dimension of a subterraneous, an aerial, or celestial space, determined by its position to bodies, and which is vulgarly taken for immoveable space; as the distance of a subterraneous, an aerial, or celestial space, determined by its position in respect of the earth. Absolute and relative space are the same in figure and magnitude; but they do not remain always numerically the same. For if the earth, for instance, moves, a space of our air which, relatively and in respect of the earth, remains always the same, will at one time be one part of the absolute space into which the air passes; at another time it will be another part of the same; and so, absolutely understood, it will be perpetually mutable.

6 Place defined. III. Place is a part of space which a body takes up; and is, according to the space, either absolute or relative. Our author says it is *part* of space; not the situation, nor the external surface of the body. For the places of equal solids are always equal; but their superficies, by reason of their dissimilar figures, are often unequal. Positions properly have no quantity, nor are they so much the places themselves as the properties of places. The motion of the whole is the same thing with the sum of the motions of the parts; that is, the translation of the whole out of its place is the same thing with the sum of the translations of the parts out of their places: and therefore the place of the whole is the same thing with the sum of the places of the parts; and for that reason it is internal, and in the whole body.

7 Of motion. IV. Absolute motion is the translation of a body from one absolute place into another, and relative motion the translation from one relative place into another. Thus, in a ship under sail, the relative place of a body is that part of the ship which the body possesses, or that part of its cavity which the body fills, and which therefore moves together with the ship; and relative rest is the continuance of the body in the same part of the ship, or of its cavity. But real absolute rest is the continuance of the body in the same part of that immoveable space in which the ship itself, its cavity, and all that it contains, is moved. Wherefore, if the earth is really at rest, the body which relatively rests in the ship will really and absolutely move with the same velocity which the ship has on the earth. But if the earth also moves, the true and absolute motion of the body will arise, partly from the true motion of the earth in immoveable space; partly from the relative motion of the ship on the earth: and if the body moves also relatively in the ship, its true motion will arise partly from the true motion of the earth in immoveable space, and partly from the relative motions as well of the ship on the earth, as of the body in the ship; and from these relative motions will arise the relative motion of the body on the earth. As if that part of the earth where the ship is, was truly moved towards the east, with a velocity of 10010 parts; while the ship itself with a fresh gale is carried towards the west, with a velocity expressed by 10 of these parts; but a sailor walks in the ship towards the east with one part of the said velocity: then the sailor will be moved truly and absolutely in immoveable space towards the east with a velocity of 1001 parts; and relatively on the earth towards the west, with a velocity of 9 of those parts.

Absolute time, in astronomy, is distinguished from relative, by the equation or correction of the vulgar time. For the natural days are truely unequal, though they are commonly considered as equal, and used for a measure of time: astronomers correct this inequality for their more accurate deducing of the celestial motions. It may be that there is no such thing as an equable motion whereby time may be accurately measured. All motions may be accelerated or retarded; but the true or equable progress of absolute time is liable to no change. The duration or perseverance of the existence of things remains the same, whether the motions are swift or slow, or none at all; and therefore ought to be distinguished from what are only sensible measures thereof, and out of which we collect it by means of the astronomical equation. The necessity of which equation for determining the times of a phenomenon is evinced, as well from the experiments of the pendulum-clock, as by eclipses of the satellites of Jupiter.

As the order of the parts of time is immutable, so also is the order of the parts of space. Suppose those parts to be moved out of their places, and they will be moved (if we may be allowed the expression) out of themselves. For times and spaces are, as it were, the places of themselves as of all other things. All things are placed in time as to order of succession; and in space as to order of situation. It is from their essence or nature that they are places; and that the primary places of things should be moveable, is absurd. These are therefore the absolute places; and translations out of those places are the only absolute motions. 8 Immutability of time and space.

But because the parts of space cannot be seen, or distinguished from one another by the senses, therefore in their stead we use sensible measures of them. For, from the positions and distances of things from any body, considered as immoveable, we define all places; and then with respect to such places, we estimate all motions, considering bodies as transferred from some of those places into others. And so, instead of absolute places and motions, we use relative ones; and that without any inconvenience in common affairs: but in philosophical disquisitions we ought to abstract from our senses, and consider things themselves distinct from what are only sensible measures of them. For it may be, that there is no body really at rest, to which the places and motions of others may be referred.

But we may distinguish rest and motion, absolute and relative, one from the other by their properties, causes, and effects. It is a property of rest, that bodies really at rest do rest in respect of each other. And therefore, as it is possible, that, in the remote regions

gions of the fixed ſtars, or perhaps far beyond them, there may be ſome body abſolutely at reſt, but impoſſible to know from the poſition of bodies to one another in our regions, whether any of theſe do keep the ſame poſition to that remote body; it follows, that abſolute reſt cannot be determined from the poſition of bodies in our regions.

9
Of the motion of different bodies with reſpect to one another.

It is a property of motion, that the parts which retain given poſitions to their wholes do partake of the motions of their wholes. For all parts of revolving bodies endeavour to recede from the axis of motion; and the impetus of bodies moving forwards ariſes from the joint impetus of all the parts. Therefore if ſurrounding bodies are moved, thoſe that are relatively at reſt within them will partake of their motion. Upon which account the true and abſolute motion of a body cannot be determined by the tranſlation of it from thoſe only which ſeem to reſt; for the external bodies ought not only to appear at reſt, but to be really at reſt. For otherwiſe all included bodies, beſide their tranſlation from near the ſurrounding ones, partake likewiſe of their true motions; and though that tranſlation was not made, they would not really be at reſt, but only ſeem to be ſo. For the ſurrounding bodies ſtand in the like relation to the ſurrounded, as the exterior part of a whole does to the interior, or as the ſhell does to the kernel; but if the ſhell moves, the kernel will alſo move, as being part of the whole, without any removal from near the ſhell.

A property near akin to the preceding is, that if a place is moved, whatever is placed therein moves along with it; and therefore a body which is moved from a place in motion, partakes alſo of the motion of its place. Upon which account all motions from places in motion, are no other than parts of entire and abſolute motions; and every entire motion is compoſed out of the motion of the body out of its firſt place, and the motion of this place out of its place; and ſo on, until we come to ſome immoveable place, as in the above-mentioned example of the ſailor. Wherefore entire and abſolute motions can be no otherwiſe determined than by immoveable places. Now, no other places are immoveable but thoſe that from infinity to infinity do all retain the ſame given poſitions one to another; and upon this account muſt ever remain unmoved, and do thereby conſtitute what we call *immoveable ſpace*.

The cauſes by which true and relative motions are diſtinguiſhed one from the other, are the forces impreſſed upon bodies to generate motion. True motion is neither generated nor altered, but by ſome force impreſſed upon the body moved: but relative motion may be generated or altered without any force impreſſed upon the body. For it is ſufficient only to impreſs ſome force on other bodies with which the former is compared, that, by their giving way, that relation may be changed, in which the relative reſt or motion of the other body did conſiſt. Again, true motion ſuffers always ſome change from any force impreſſed upon the moving body; but relative motion does not neceſſarily undergo any change by ſuch force. For if the ſame forces are likewiſe impreſſed on thoſe other bodies with which the compariſon is made, that the relative poſition may be preſerved; then that condition will be preſerved; in which the relative motion conſiſts. And therefore any relative motion may be changed when the true motion remains unaltered, and the relative may be preſerved when the true motion ſuffers ſome change. Upon which account true motion does by no means conſiſt in ſuch relations. 10

Abſolute and relative motion diſtinguiſhed.

The effects which diſtinguiſh abſolute from relative motion are, the forces of receding from the axis of circular motion. For there are no ſuch forces in a circular motion purely relative: but, in a true and abſolute circular motion, they are greater or leſs according to the quantity of the motion. If a veſſel, hung by a long cord, is ſo often turned about that the cord is ſtrongly twiſted, then filled with water, and let go, it will be whirled about the contrary way; and while the cord is untwiſting itſelf, the ſurface of the water will at firſt be plain, as before the veſſel began to move; but the veſſel, by gradually communicating its motion to the water, will make it begin ſenſibly to revolve, and recede by little and little from the middle, and aſcend to the ſides of the veſſel, forming itſelf into a concave figure; and the ſwifter the motion becomes, the higher will the water riſe, till at laſt, performing its revolutions in the ſame times with the veſſel, it becomes relatively at reſt in it. This aſcent of the water ſhews its endeavour to recede from the axis of its motion; and the true and abſolute circular motion of the water, which is here directly contrary to the relative, diſcovers itſelf, and may be meaſured by this endeavour. At firſt, when the relative motion in the water was greateſt, it produced no endeavour to recede from the axis; the water ſhewed no tendency to the circumference, nor any aſcent towards the ſides of the veſſel, but remained of a plain ſurface; and therefore its true circular motion had not yet begun. But afterwards, when the relative motion of the water had decreaſed, the aſcent thereof towards the ſides of the veſſel, proved its endeavour to recede from the axis; and this endeavour ſhewed the real circular motion of the water perpetually increaſing, till it had acquired its greateſt quantity, when the water reſted relatively in the veſſel. And therefore this endeavour does not depend upon any tranſlation of the water in reſpect of the ambient bodies; nor can true circular motion be defined by ſuch tranſlations. There is only one real circular motion of any one revolving body, correſponding to only one power of endeavouring to recede from its axis of motion, as its proper and adequate effect: but relative motions in one and the ſame body are innumerable, according to the various relations it bears to external bodies; and, like other relations, are altogether deſtitute of any real effect, otherwiſe than they may perhaps participate of that only true motion. And therefore, in the ſyſtem which ſuppoſes that our heavens, revolving below the ſphere of the fixed ſtars, carry the planets along with them, the ſeveral parts of thoſe heavens and the planets, which are indeed relatively at reſt in their heavens, do yet really move. For they change their poſition one to another, which never happens to bodies truly at reſt; and being carried together with the heavens, participate of their motions, and, as parts of revolving wholes, endeavour to recede from the axis of their motion.

Wherefore relative quantities are not the quantities themſelves whoſe names they bear, but thoſe ſenſible mea-

meaſures of them, either accurate or inaccurate, which are commonly uſed inſtead of the meaſured quantities themſelves. And then, if the meaning of words is to be determined by their uſe, by the names *time*, *ſpace*, *place*, and *motion*, their meaſures are properly to be underſtood; and the expreſſion will be unuſual and purely mathematical, if the meaſured quantities themſelves are meant.

It is indeed a matter of great difficulty to diſcover, and effectually to diſtinguiſh, the true motions of particular bodies from thoſe that are only apparent: becauſe the parts of that immoveable ſpace in which thoſe motions are performed, do by no means come under the obſervation of our ſenſes. Yet we have ſome things to direct us in this intricate affair; and theſe ariſe partly from the apparent motions which are the difference of the true motions, partly from the forces which are the cauſes and effects of the true motions. For inſtance, if two globes, kept at a given diſtance one from the other by means of a cord that connects them, were revolved about their common centre of gravity; we might, from the tenſion of the cord, diſcover the endeavour of the globes to recede from the axis of motion, and from thence we might compute the quantity of their circular motions. And then, if any equal forces ſhould be impreſſed at once on the alternate faces of the globes to augment or diminiſh their circular motions, from the increaſe or decreaſe of the tenſion of the cord we might infer the increment or decrement of their motions; and thence would be found on what faces thoſe forces ought to be impreſſed, that the motions of the globes might be moſt augmented; that is, we might diſcover their hindermoſt faces, or thoſe which follow in the circular motion. But the faces which follow being known, and conſequently the oppoſite ones that precede, we ſhould likewiſe know the determination of their motions. And thus we might find both the quantity and determination of this circular motion, even in an immenſe vacuum, where there was nothing external or ſenſible, with which the globes might be compared. But now, if in that ſpace ſome remote bodies were placed that kept always a given poſition one to another, as the fixed ſtars do in our regions; we could not indeed determine from the relative tranſlation of the globes among thoſe bodies, whether the motion did belong to the globes or to the bodies. But if we obſerved the cord, and found that its tenſion was that very tenſion which the motions of the globes required, we might conclude the motion to be in the globes, and the bodies to be at reſt; and then, laſtly, from the tranſlation of the globes among the bodies, we ſhould find the determination of their motions.

Having thus explained himſelf, Sir Iſaac propoſes to ſhow how we are to collect the true motions from their cauſes, effects, and apparent differences; and *vice verſa*, how, from the motions, either true or apparent, we may come to the knowledge of their cauſes and effects. In order to this, he lays down the following axioms or laws of motion.

12 Laws of motion.

1. Every body perſeveres in its ſtate of reſt, or of uniform motion in a right line, unleſs it is compelled to change that ſtate by forces impreſſed upon it.—Sir Iſaac's proof of this action is as follows: "Projectiles perſevere in their motions, ſo far as they are not retarded by the reſiſtance of the air, or impelled downwards by the force of gravity. A top, whoſe parts, by their coheſion, are perpetually drawn aſide from rectilinear motions, does not ceaſe its rotation otherwiſe than as it is retarded by the air. The greater bodies of the planets and comets, meeting with leſs reſiſtance in more free ſpaces, preſerve their motions, both progreſſive and circular, for a much longer time."—Notwithſtanding this demonſtration, however, the axiom hath been violently diſputed. It hath been argued, that bodies continue in their ſtate of motion becauſe they are ſubjected to the continual impulſe of an inviſible and ſubtile fluid, which always pours in from behind, and of which all places are full. They affirm that motion is as natural to this fluid as reſt is to all other matter. They ſay, moreover, that it is impoſſible we can know in what manner a body would be influenced by moving forces if it was entirely deſtitute of gravity. According to what we can obſerve, the momentum of a body, or its tendency to move, depends very much on its gravity. A heavy cannon-ball will fly to a much greater diſtance than a light one, though both are actuated by an equal force. It is by no means clear therefore, that a body totally deſtitute of gravity would have any proper momentum of its own; and if it had no momentum, it could not continue its motion for the ſmalleſt ſpace of time after the moving power was withdrawn. Some have imagined that matter was capable of beginning motion of itſelf, and conſequently that the axiom was falſe; becauſe we ſee plainly that matter in ſome caſes hath a tendency to change from a ſtate of motion to a ſtate of reſt, and from a ſtate of reſt to a ſtate of motion. A paper appeared on this ſubject in the firſt volume of the Edinburgh Phyſical and Literary Eſſays; but the hypotheſis never gained any ground.

13 Objections to the firſt law.

2. The alteration of motion is ever proportional to the motive force impreſſed; and is made in the direction of the right line in which that force is impreſſed. Thus, if any force generates a certain quantity of motion, a double force will generate a double quantity, whether that force be impreſſed all at once, or in ſucceſſive moments.

14 Objections to the third law.

3. To every action there is always oppoſed an equal re-action: or the mutual actions of two bodies upon each other are always equal, and directed to contrary parts.—This axiom is alſo diſputed by many. In the abovementioned paper in the Phyſical Eſſays, the author endeavours to make a diſtinction between re-action and reſiſtance; but this cannot be ſufficiently explained, and therefore the hypotheſis hath not been adopted. Others grant that Sir Iſaac's axiom is very true in reſpect to terreſtrial ſubſtances; but they affirm, that, in theſe, both action and re-action are the effects of gravity. Subſtances void of gravity would have no momentum; and without this they could not act; they would be moved by the leaſt force, and therefore could not reſiſt or re-act. If therefore there is any fluid which is the cauſe of gravity, though ſuch fluid could act upon terreſtrial ſubſtances, yet theſe could not re-act upon it; becauſe they have no force of their own, but depend entirely upon it for their momentum. In this manner, ſay they, we may conceive that the planets circulate, and all the operations of nature are carried on by means of a ſubtile fluid; which being per-

fectly active, and the rest of matter altogether passive, there is neither resistance, nor loss of motion.

From the preceding axiom Sir Isaac draws the following corollaries.

1. A body by two forces conjoined will describe the diagonal of a parallelogram in the same time that it would describe the sides by those forces apart.

2. Hence we may explain the composition of any one direct force out of any two oblique ones, *viz.* by making the two oblique forces the sides of a parallelogram, and the direct one the diagonal.

3. The quantity of motion, which is collected by taking the sum of the motions directed towards the same parts, and the difference of those that are directed to contrary parts, suffers no change from the action of bodies among themselves; because the motion which one body loses is communicated to another: and if we suppose friction and the resistance of the air to be absent, the motion of a number of bodies which mutually impelled one another would be perpetual, and its quantity always equal.

4. The common centre of gravity of two or more bodies does not alter its state of motion or rest by the actions of the bodies among themselves; and therefore the common centre of gravity of all bodies acting upon each other (excluding outward actions and impediments) is either at rest, or moves uniformly in a right line.

5. The motions of bodies included in a given space are the same among themselves, whether that space is at rest, or moves uniformly forward in a right line without any circular motion. The truth of this is evidently shewn by the experiment of a ship; where all motions happen after the same manner, whether the ship is at rest, or proceeds uniformly forward in a straight line.

6. If bodies, any how moved among themselves, are urged in the direction of parallel lines by equal accelerative forces, they will all continue to move among themselves, after the same manner as if they had been urged by no such forces.

The whole of the mathematical part of the Newtonian philosophy depends on the following lemmas; of which the first is the principal.

Lem. I. Quantities, and the ratios of quantities, which in any finite time converge continually to equality, and before that time approach nearer the one to the other than by any given difference, become ultimately equal. If you deny it; suppose them to be ultimately unequal, and let D be their ultimate difference. Therefore they cannot approach nearer to equality than by that given difference D; which is against the supposition.

16 Objections to the first lemma.

Concerning the meaning of this lemma philosophers are not agreed; and unhappily it is the very fundamental position on which the whole of the system rests. Many objections have been raised to it by people who supposed themselves capable of understanding it. They say, that it is impossible we can come to an end of any infinite series, and therefore that the word *ultimate* can in this case have no meaning. In some cases the lemma is evidently false. Thus, suppose there are two quantities of matter A and B, the one containing half a pound, and the other a third part of one. Let both be continually divided by 2; and though their ratio, or the proportion of the one to the other, doth not vary, yet the difference between them perpetually becomes less, as well as the quantities themselves, until both the difference and quantities themselves become less than any assignable quantity; yet the difference will never totally vanish, nor the quantities become equal, as is evident from the two following series.

$$\frac{1}{2}\ \frac{1}{4}\ \frac{1}{8}\ \frac{1}{16}\ \frac{1}{32}\ \frac{1}{64}\ \frac{1}{128}\ \frac{1}{256}\ \frac{1}{512}\ \frac{1}{1024},\ \&c.$$
$$\frac{1}{3}\ \frac{1}{6}\ \frac{1}{12}\ \frac{1}{24}\ \frac{1}{48}\ \frac{1}{96}\ \frac{1}{192}\ \frac{1}{384}\ \frac{1}{768}\ \frac{1}{1536},\ \&c.$$
$$\text{Diff. } \frac{1}{6}\ \frac{1}{12}\ \frac{1}{24}\ \frac{1}{48}\ \frac{1}{96}\ \frac{1}{192}\ \frac{1}{384}\ \frac{1}{768}\ \frac{1}{1536}\ \frac{1}{3072},\ \&c.$$

Thus we see, that though the difference is continually diminishing, and that in a very large proportion, there is no hope of its vanishing, or the quantities becoming equal. In like manner, let us take the proportions or ratios of quantities, and we shall be equally unsuccessful. Suppose two quantities of matter, one containing 8 and the other 10 pounds; these quantities already have to each other the ratio of 8 to 10, or of 4 to 5; but let us add 2 continually to each of them, and though the ratios continually come nearer to that of equality, it is in vain to hope for a perfect coincidence. Thus,

$$8\ \ 10\ \ 12\ \ 14\ \ 16\ \ 18\ \ 20\ \ 22\ \ 24,\ \&c.$$
$$10\ \ 12\ \ 14\ \ 16\ \ 18\ \ 20\ \ 22\ \ 24\ \ 26,\ \&c.$$
$$\text{Ratio } \frac{4}{5}\ \frac{5}{6}\ \frac{6}{7}\ \frac{7}{8}\ \frac{8}{9}\ \frac{0}{10}\ \frac{10}{11}\ \frac{11}{12}\ \frac{12}{13},\ \&c.$$

For this and his other lemmas Sir Isaac makes the following apology. 17 Answered.

"These lemmas are premised, to avoid the tediousness of deducing perplexed demonstrations *ad absurdum*, according to the method of ancient geometers. For demonstrations are more contracted by the method of indivisibles: but because the hypothesis of indivisibles seems somewhat harsh, and therefore that method is reckoned less geometrical, I chose rather to reduce the demonstrations of the following propositions to the first and last sums and ratios of nascent and evanescent quantities, that is, to the limits of those sums and ratios; and so to premise, as short as I could, the demonstrations of those limits. For hereby the same thing is performed as by the method of indivisibles; and now those principles being demonstrated, we may use them with more safety. Therefore, if hereafter I should happen to consider quantities as made up of particles, or should use little curve lines for right ones; I would not be understood to mean indivisibles, but evanescent divisible quantities; not the sums and ratios of determinate parts, but always the limits of sums and ratios; and that the force of such demonstrations always depends on the method laid down in the foregoing lemmas.

"Perhaps it may be objected, that there is no ultimate proportion of evanescent quantities, because the proportion before the quantities have vanished, is not the ultimate, and, when they are vanished, is none. But by the same argument it may be alleged, that a body arriving at a certain place, and there stopping, has no ultimate velocity; because the velocity before the body comes to the place is not its ultimate velocity; when it is arrived, it has none. But the answer is easy: for by the ultimate velocity is meant that with which the body is moved, neither before it arrives at its place and the motion ceases, nor after; but at the very instant it arrives; that is, that velocity with which the body arrives at its last place, and with which the motion ceases. And in like manner, by the ultimate ratio of evanescent quantities is to be under-

underftood the ratio of the quantities, not before they vanifh, nor afterwards, but with which they vanifh. In like manner, the firft ratio of nafcent quantities is that with which they begin to be. And the firft or laft fum is that with which they begin and ceafe to be (or to be augmented and diminifhed). There is a limit which the velocity at the end of the motion may attain, but not exceed; and this is the ultimate velocity. And there is the like limit in all quantities and proportions that begin and ceafe to be. And, fince fuch limits are certain and definite, to determine the fame is a problem ftrictly geometrical. But whatever is geometrical we may be allowed to make ufe of in determining and demonftrating any other thing that is likewife geometrical.

"It may be alfo objected, that if the ultimate ratios of evanefcent quantities are given, their ultimate magnitudes will alfo be given; and fo all quantities will confift of indivifibles, which is contrary to what Euclid has demonftrated concerning incommenfurables, in the 10th book of his Elements. But this objection is founded on a falfe fuppofition. For thofe ultimate ratios with which quantities vanifh are not truly the ratios of ultimate quantities, but limits towards which the ratios of quantities decreafing continually approach."

LEM. II. If in any figure A a c E (Pl. CCIV. fig. 2.) terminated by the right line Aa, AE, and the curve a c E, there be infcribed any number of parallelograms Ab, Bc, Cd, &c. comprehended under equal bafes AB, BC, CD, &c. and the fides Bb, Cc, Dd, &c. parallel to one fide Aa of the figure; and the parallelograms a K b l, b L c m, c M d n, &c. are completed. Then if the breadth of thofe parallelograms be fuppofed to be diminifhed, and their number augmented *in infinitum*; the ultimate ratios which the infcribed figure A K b L c M d D, the circumfcribed figure A a l b m c n d o E, and curvilinear figure A a b c d E, will have to one another, are ratios of equality. —For the difference of the infcribed and circumfcribed figures is the fum of the parallelograms K l, L m, M n, D o; that is, (from the equality of all their bafes), the rectangle under one of their bafes K b, and the fum of their altitudes A a, that is, the rectangle A B l a. But this rectangle, becaufe its breadth AB is fuppofed diminifhed *in infinitum*, becomes lefs than any given fpace. And therefore, by lem. 1. the figures infcribed and circumfcribed become ultimately equal the one to the other; and much more will the intermediate curvilinear figure be ultimately equal to either.

LEM. III. The fame ultimate ratios are alfo ratios of equality, when the breadths AB, BC, DC, &c. of the parallelograms are unequal, and are all diminifhed *in infinitum*.—The demonftration of this differs but little from that of the former.

In his fucceeding lemmas, Sir Ifaac goes on to prove, in a manner fimilar to the above, that the ultimate ratios of the fine, chord, and tangent of arcs infinitely diminifhed, are ratios of equality, and therefore that in all our reafonings about thefe we may fafely ufe the one for the other:—that the ultimate form of evanefcent triangles made by the arc, chord, and tangent, is that of fimilitude, and their ultimate ratio is that of equality; and hence, in reafonings about ultimate ratios, we may fafely ufe thefe triangles for each other, whether made with the fine, the arc, or the tangent.—He then fhews fome properties of the ordinates of curvilinear figures; and proves that the fpaces which a body defcribes by any finite force urging it, whether that force is determined and immutable, or is continually augmented or continually diminifhed, are, in the very beginning of the motion, one to the other in the duplicate ratio of the powers. And laftly, having added fome demonftrations concerning the evanefcence of angles of contact, he proceeds to lay down the mathematical part of his fyftem, and which depends on the following theorems.

THEOR. I. The areas which revolving bodies defcribe by radii drawn to an immoveable centre of force, lie in the fame immoveable planes, and are proportional to the times in which they are defcribed.—For, fuppofe the time to be divided into equal parts, and in the firft part of that time, let the body by its innate force defcribe the right line AB (fig. 3.); in the fecond part of that time, the fame would, by law 1. if not hindered, proceed directly to c along the line Bc = AB; fo that by the radii AS, BS, c S, drawn to the centre, the equal areas ASB, B S c, would be defcribed. But, when the body is arrived at B, fuppofe the centripetal force acts at once with a great impulfe, and, turning afide the body from the right line B c, compels it afterwards to continue its motion along the right line BC. Draw c C parallel to BS, meeting BC in C; and at the end of the fecond part of the time, the body, by cor. 1. of the laws, will be found in C, in the fame plane with the triangle ASB. Join SC; and becaufe SB and c C are parallel, the triangle SBC will be equal to the triangle SBC, and therefore alfo to the triangle SAB. By the like argument, if the centripetal force acts fucceffively in C, D, E, &c. and makes the body in each fingle particle of time to defcribe the right lines CD, DE, EF, &c. they will all lie in the fame plane; and the triangle SCD will be equal to the triangle SBC, and SDE to SCD, and SEF to SDE. And therefore, in equal times, equal areas are defcribed in one immoveable plane; and, by compofition, any fums SADS, SAFS, of thofe areas are, one to the other, as the times in which they are defcribed. Now, let the number of thofe triangles be augmented, and their fize diminifhed *in infinitum*; and then, by the preceding lemmas, their ultimate perimeter ADF will be a curve line: and therefore the centripetal force by which the body is perpetually drawn back from the tangent of this curve will act continually; and any defcribed areas SADS, SAFS, which are always proportional to the times of defcription, will, in this cafe alfo, be proportional to thofe times. Q. E. D.

COR. 1. The velocity of a body attracted towards an immoveable centre, in fpaces void of refiftance is reciprocally as the perpendicular let fall from that centre on the right line which touches the orbit. For the velocities in thefe places A, B, C, D, E, are as the bafes AB, BC, DE, EF, of equal triangles; and thefe bafes are reciprocally as the perpendiculars let fall upon them.

COR. 2. If the chords AB, BC, of two arcs fucceffively defcribed in equal times by the fame body, in fpaces void of refiftance, are completed into a pa-

parallelogram ABCV, and the diagonal BV of this parallelogram, in the pofition which it ultimately acquires when thofe arcs are diminifhed *in infinitum* is produced both ways, it will pafs through the centre of force.

COR. 3. If the chords AB, BC, and DE, EF, of arcs defcribed in equal times, in fpaces void of refiftance are completed into the parallelograms ABCV, DEFZ, the forces in B and E are one to the other in the ultimate ratio of the diagonals BV, EZ, when thofe arcs are diminifhed *in infinitum*. For the motions BC and EF of the body (by cor. 1. of the laws), are compounded of the motions B*c*, BV and E*f*, EZ; but BV and EZ, which are equal to C*c*= and F*f*, in the demonftration of this propofition, were generated by the impulfes of the centripetal force in B and E, and are therefore proportional to thofe impulfes.

COR. 4. The forces by which bodies, in fpaces void of refiftance, are drawn back from rectilinear motions, and turned into curvilinear orbits, are one to another as the verfed fines of arcs defcribed in equal times; which verfed fines tend to the centre of force, and bifect the chords when thefe arcs are diminifhed to infinity. For fuch verfed fines are the halfs of the diagonals mentioned in cor. 3.

COR. 5. And therefore thofe forces are to the force of gravity, as the faid verfed fines to the verfed fines perpendicular to the horizon of thofe parabolic arcs which projectiles defcribe in the fame time.

COR. 6. And the fame things do all hold good (by cor. 5. of the laws) when the planes in which the bodies are moved, together with the centres of force, which are placed in thofe planes, are not at reft, but move uniformly forward in right lines.

THEOR. II. Every body that moves in any curve line defcribed in a plane, and, by a radius drawn to a point either immoveable or moving forward with an uniform rectilinear motion, defcribes about that point areas proportional to the times, is urged by a centripetal force directed to that point.

CASE I. For every body that moves in a curve line is (by law 1.) turned afide from its rectilinear courfe by the action of fome force that impels it; and that force by which the body is turned off from its rectilinear courfe, and made to defcribe in equal times the leaft equal triangles SAB, SBC, SCD, &c. about the immoveable point S, (by Prop. 40. E. 1. and law 2.) acts in the place B according to the direction of a line parallel to C; that is, in the direction of the line BS; and in the place C according to the direction of a line parallel to d D, that is, in the direction of the line CS, &c.; and therefore acts always in the direction of lines tending to the immoveable point S. Q. E. D.

CASE II. And (by cor. 5. of the laws) it is indifferent whether the fuperficies in which a body defcribes a curvilinear figure be quiefcent, or moves together with the body, the figure defcribed, and its point S, uniformly forward in right lines.

COR. 1. In non-refifting fpaces or mediums, if the areas are not proportional to the times, the forces are not directed to the point in which the radii meet; but deviate therefrom *in confequentia*, or towards the parts to which the motion is directed, if the defcription of the areas is accelerated; but *in antecedentia* if retarded.

COR. 2. And even in refifting mediums, if the defcription of the areas is accelerated, the directions of the forces deviate from the point in which the radii meet, towards the parts to which the motion tends.

SCHOLIUM.

A body may be urged by a centripetal force compounded of feveral forces. In which cafe the meaning of the propofition is, that the force which refults out of all tends to the point S. But if any force acts perpetually in the direction of lines perpendicular to the defcribed furface, this force will make the body to deviate from the plane of its motion, but will neither augment nor diminifh the quantity of the defcribed furface; and is therefore not to be neglected in the compofition of forces.

THEOR. III. Every body that, by a radius drawn to the centre of another body, howfoever moved, defcribes areas about that centre proportional to the times, is urged by a force compounded out of the centripetal forces tending to that other body, and of all the accelerative force by which that other body is impelled.—The demonftration of this is a natural confequence of the theorem immediately preceding.

Hence, if the one body L, by a radius drawn to the other body T, defcribes areas proportional to the times, and from the whole force by which the firft body L is urged, (whether that force is fimple, or, according to cor. 2. of the laws, componnded out of feveral forces), we fubduct that whole accelerative force by which the other body is urged; the whole remaining force by which the firft body is urged will tend to the other body T, as its centre.

And *vice verfa*, if the remaining force tends nearly to the other body T, thofe areas will be nearly proportional to the times.

If the body L, by a radius drawn to the other body T, defcribes areas, which, compared with the times, are very unequal; and that other body T be either at reft, or moves uniformly forward in a right line, the action of the centripetal force tending to that other body T is either none at all, or it is mixed and combined with very powerful actions of other forces: and the whole force compounded of them all, if they are many, is directed to another (immoveable or moveable) centre. The fame thing obtains when the other body is actuated by any other motion whatever; provided that centripetal force is taken which remains after fubducting that whole force acting upon that other body T.

SCHOLIUM.

Becaufe the equable defcription of areas indicates that a centre is refpected by that force with which the body is moft affected, and by which it is drawn back from its rectilinear motion, and retained in its orbit, we may always be allowed to ufe the equable defcription of areas as an indication of a centre about which all circular motion is performed in free fpaces.

THEOR. IV. The centripetal forces of bodies which by equable motions defcribe different circles, tend to the centres of the fame circles; and are one to the other as the fquares of the arcs defcribed in equal times applied to the radii of circles,—For thefe forces tend

Newtonian Philosophy

tend to the centres of the circles, (by theor. 2. and cor. 2. theor. 1.) and are to one another as the verfed fines of the leaft arcs defcribed in equal times, (by cor. 4. theor. 1.) that is, as the fquares of the fame arcs applied to the diameters of the circles, by one of the lemmas; and therefore, fince thofe arcs are as arcs defcribed in any equal times, and the diameters are as the radii, the forces will be as the fquares of any arcs defcribed in the fame time, applied to the radii of the circles. Q. E. D.

Cor. 1. Therefore, fince thofe arcs are as the velocities of the bodies, the centripetal forces are in a ratio compounded of the duplicate ratio of the velocities directly, and of the fimple ratio of the radii inverfely.

Cor. 2. And fince the periodic times are in a ratio compounded of the ratio of the radii directly, and the ratio of the velocities inverfely; the centripetal forces are in a ratio compounded of the ratio of the radii directly, and the duplicate ratio of the periodic times inverfely.

Cor. 3. Whence, if the periodic times are equal, and the velocities therefore as the radii, the centripetal forces will be alfo as the radii; and the contrary.

Cor. 4. If the periodic times and the velocities are both in the fubduplicate ratio of the radii, the centripetal forces will be equal among themfelves; and the contrary.

Cor. 5. If the periodic times are as the radii, and therefore the velocities equal, the centripetal forces will be reciprocally as the radii; and the contrary.

Cor. 6. If the periodic times are in the fefquiplicate ratio of the radii, and therefore the velocities reciprocally in the fubduplicate ratio of the radii, the centripetal forces will be in the duplicate ratio of the radii inverfely; and the contrary.

Cor. 7. And univerfally, if the periodic time is as any power R^n of the radius R, and therefore the velocity reciprocally as the power R^{n-1} of the radius, the centripetal force will be reciprocally as the power R^{2n-2} of the radius; and the contrary.

Cor. 8. The fame things all hold concerning the times, the velocities, and forces, by which bodies defcribe the fimilar parts of any fimilar figures, that have their centres in a fimilar pofition within thofe figures, as appears by applying the demonftrations of the preceding cafes to thofe. And the application is eafy, by only fubftituting the equable defcription of areas in the place of equable motion, and ufing the diftances of the bodies from the centres inftead of the radii.

Cor. 9. From the fame demonftration it likewife follows, that the arc which a body uniformly revolving in a circle by means of a given centripetal force defcribes in any time, is a mean proportional between the diameter of the circle, and the fpace which the fame body, falling by the fame given force, would defcend through in the fame given time.

"By means of the preceding propofition and its corollaries, (fays Sir Ifaac), we may difcover the proportion of a centripetal force to any other known force, fuch as that of gravity. For if a body by means of its gravity revolves in a circle concentric to the earth, this gravity is the centripetal force of that body. But from the defcent of heavy bodies, the time of one entire revolution, as well as the arc defcribed in any given time, is given (by cor. 9. of this theorem). And by fuch propofitions Mr Huygens, in his excellent book *De Horologio Ofcillatorio*, has compared the force of gravity with the centrifugal forces of revolving bodies.

The preceding propofition may alfo be demonftrated in the following manner. In any circle fuppofe a polygon to be infcribed of any number of fides. And if a body, moved with a given velocity along the fides of the polygon, is reflected from the circle at the feveral angular points; the force with which, at every reflection, it ftrikes the circle will be as its velocity: and therefore the fum of the forces, in a given time, will be as that velocity and the number of reflections conjunctly; that is, (if the fpecies of the polygon be given), as the length defcribed in that given time, and increafed or diminifhed in the ratio of the fame length to the radius of the circle; that is, as the fquare of that length applied to the radius; and therefore, if the polygon, by having its fides diminifhed *in infinitum*, coincides with the circle, as the fquare of the arc defcribed in a given time applied to the radius. This is the centrifugal force, with which the body impels the circle; and to which the contrary force, wherewith the circle continually repels the body towards the centre, is equal.

On thefe principles hangs the whole of Sir Ifaac Newton's mathematical philofophy. He now fhews how to find the centre to which the forces impelling any body are directed, having the velocity of the body given: and finds the centrifugal force to be always as the verfed fine of the nafcent arc directly, and as the fquare of the time inverfely; or directly as the fquare of the velocity, and inverfely as the chord of the nafcent arc. From thefe premiffes he deduces the method of finding the centripetal force directed to any given point when the body revolves in a circle; and this whether the central point is near or at an immenfe diftance; fo that all the lines drawn from it may be taken for parallels. The fame thing he fhews with regard to bodies revolving in fpirals, ellipfes, hyperbolas, or parabolas.—Having the figures of the orbits given, he fhews alfo how to find the velocities and moving powers; and, in fhort, folves all the moft difficult problems relating to the celeftial bodies with an aftonifhing degree of mathematical fkill. Thefe problems and demonftrations are all contained in the firft book of the *Principia*: but to give an account of them here would exceed our limits; neither would many of them be intelligible, excepting to firft-rate mathematicians.

18 Rules for philofophical reafoning.

In the fecond book Sir Ifaac treats of the properties of fluids, and their powers of refiftance; and here he lays down fuch principles as entirely overthrow the doctrine of Des Cartes's vortices, which was the fafhionable fyftem in his time. In the third book, he begins particularly to treat of the natural phenomena, and apply to them the mathematical principles formerly demonftrated; and, as a neceffary preliminary to this part, he lays down the following rules for reafoning in natural philofophy.

1. We are to admit no more caufes of natural things

things than fuch as are both true and fufficient to explain their natural appearances.

2. Therefore to the fame natural effects we muft always affign, as far as poffible, the fame caufes.

3. The qualities of bodies which admit neither intenfion nor remiffion of degrees, and which are found to belong to all bodies within the reach of our experiments, are to be efteemed the univerfal qualities of all bodies whatfoever.

4. In experimental philofophy, we are to look upon propofitions collected by general induction from phenomena as accurately or very nearly true, notwithftanding any contrary hypothefes that may be imagined, till fuch time as other phenomena occur, by which they may either be made more accurate, or liable to exceptions.

The phenomena firft confidered, are, 1. That the fatellites of Jupiter by radii drawn to the centre of their primary, defcribe areas proportional to the times of their defcription; and that their periodic times, the fixed ftars being at reft, are in the fefquiplicate ratio of their diftances from its centre. 2. The fame thing is likewife obferved of the phenomena of Saturn. 3. The five primary planets, Mercury, Venus, Mars, Jupiter, and Saturn, with their feveral orbits, encompafs the fun. 4. The fixed ftars being fuppofed at reft, the periodic times of the five primary planets, and of the earth, about the fun, are in the fefquiplicate proportion of their mean diftances from the fun. 5. The primary planets, by radii drawn to the earth, defcribe areas no ways proportionable to the times: but the areas which they defcribe by radii drawn to the fun are proportional to the times of defcription. 6. The moon, by a radius drawn to the centre of the earth, defcribes an area proportional to the time of defcription. All thefe phenomena are undeniable from aftronomical obfervations, and are explained at large under the article Astronomy. The mathematical demonftrations are next applied by Sir Ifaac Newton in the following propofitions.

Prop. I. The forces by which the Satellites of Jupiter are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the centre of that planet; and are reciprocally as the fquares of the diftances of thofe fatellites from that centre. The former part of this propofition appears from theor. 2. or 3. and the latter from cor. 6. of theor. 5.; and the fame thing we are to underftand of the fatellites of Saturn.

Prop. II. The forces by which the primary planets are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the fun; and are reciprocally as the fquares of the diftances from the fun's centre. The former part of this propofition is manifeft from phænomenon 5. juft mentioned, and from theor. 2.; the latter from phænom. 4. and cor. 6. of theor. 4. But this part of the propofition is with great accuracy deducible from the quiefcence of the aphelion points. For a very fmall aberration from the reciprocal duplicate proportion would produce a motion of the apfides, fenfible in every fingle revolution, and in many of them enormoufly great.

Prop. III. The force by which the moon is retained in its orbit, tends towards the earth; and is reciprocally as the fquare of the diftance of its place from the centre of the earth. The former part of this propofition is evident from phænom. 5. and theor. 2.; the latter from phænom. 6. and theor. 2. or 3. It is alfo evident from the very flow motion of the moon's apogee; which, in every fingle revolution, amounting but to 3° 3′ *in confequentia*, may be neglected: and this more fully appears from the next propofition.

Prop. IV. The moon gravitates towards the earth, and by the force of gravity is continually drawn off from a rectilinear motion, and retained in its orbit.—The mean diftance of the moon from the earth in the fyzigies in femidiameters of the latter, is about $60\frac{1}{2}$. Let us affume the mean diftance of 60 femidiameters in the fyzigies; and fuppofe one revolution of the moon in refpect of the fixed ftars to be completed in $27^{d}.\ 7^{h}.\ 43'$, as aftronomers have determined; and the circumference of the earth to amount to 123,249,600 Paris feet. Now, if we imagine the moon, deprived of all motion, to be let go, fo as to defcend towards the earth with the impulfe of all that force by which it is retained in its orbit, it will, in the fpace of one minute of time, defcribe in its fall $15\frac{1}{4}$ Paris feet. For the verfed fine of that arc which the moon, in the fpace of one minute of time, defcribes by its mean motion at the diftance of 60 femidiameters of the earth, is nearly $15\frac{1}{12}$ Paris feet; or more accurately, 15 feet 1 inch and 1 line $\frac{4}{9}$. Wherefore fince that force, in approaching to the earth, increafes in the reciprocal duplicate proportion of the diftance; and, upon that account, at the furface of the earth is 60×60 times greater than at the moon; a body in our regions, falling with that force, ought, in the fpace of one minute of time, to defcribe $60\times60\times15\frac{1}{12}$ Paris feet; and in the fpace of one fecond of time to defcribe $15\frac{1}{12}$ of thofe feet; or, more accurately, 15 feet 1 inch, 1 line $\frac{4}{9}$. And with this very force we actually find that bodies here on earth do really defcend. For a pendulum ofcillating feconds in the latitude of Paris, will be three Paris feet and $8\frac{1}{2}$ lines in length, as Mr Huygens has obferved. And the fpace which a heavy body defcribes by falling one fecond of time, is to half the length of the pendulum in the duplicate ratio of the circumference of the circle to its diameter; and is therefore 15 Paris feet, 1 inch, 1 line $\frac{7}{9}$. And therefore the force by which the moon is retained in its orbit, becomes, at the very furface of the earth, equal to the force of gravity which we obferve in heavy bodies there. And therefore (by rule 1. and 2.) the force by which the moon is retained in its orbit is that very fame force which we commonly call *gravity*. For were gravity another force different from that, then bodies defcending to the earth with the joint impulfe of both forces, would fall with a double velocity, and, in the fpace of one fecond of time, would defcribe $30\frac{1}{6}$ Paris feet; altogether againft experience.

The demonftration of this propofition may be more diffufely explained after the following manner. Suppofe feveral moons to revolve about the earth, as in the fyftem of Jupiter or Saturn, the periodic times of thofe moons would (by the argument of induction) obferve the fame law which Kepler found to obtain among the planets; and therefore their centripetal forces would be reciprocally as the fquares of the diftances from the centre of the earth by Prop. I. Now, if the

Newtonian Philoſophy

the loweſt of theſe were very ſmall, and were ſo near the earth as almoſt to touch the tops of the higheſt mountains, the centripetal force thereof, retaining it in its orbit, would be very nearly equal to the weights of any terreſtrial bodies that ſhould be found upon the tops of theſe mountains; as may be known from the foregoing calculation. Therefore if the ſame little moon ſhould be deſerted by its centrifugal force that carries it through its orb, it would deſcend to the earth; and that with the ſame velocity as heavy bodies do actually deſcend with upon the tops of thoſe very mountains, becauſe of the equality of forces that oblige them both to deſcend. And if the force by which that loweſt moon would deſcend were different from that of gravity, and if that moon were to gravitate towards the earth, as we find terreſtrial bodies do on the tops of mountains, it would then deſcend with twice the velocity, as being impelled by both theſe forces conſpiring together. Therefore, ſince both theſe forces, that is, the gravity of heavy bodies, and the centripetal forces of the moons, reſpect the centre of the earth, and are ſimilar and equal between themſelves, they will (by rule 1. and 2.) have the ſame cauſe. And therefore the force which retains the moon in its orbit, is that very force which we commonly call *gravity;* becauſe otherwiſe this little moon at the top of a mountain muſt either be without gravity, or fall twice as ſwiftly as heavy bodies uſe to do.

Having thus demonſtrated that the moon is retained in its orbit by its gravitation towards the earth, it is eaſy to apply the ſame demonſtration to the motions of the other ſecondary planets, and of the primary planets round the ſun, and thus to ſhew that gravitation prevails throughout the whole creation; after which, Sir Iſaae proceeds to ſhew from the ſame principles, that the heavenly bodies gravitate towards each other, and contain different quantities of matter, or have different denſities in proportion to their bulks.

Prop. V. All bodies gravitate towards every planet; and the weights of bodies towards the ſame planet at equal diſtances from its centre, are proportional to the quantities of matter they contain.

It has been confirmed by many experiments, that all ſorts of heavy bodies (allowance being made for the inequality of retardation by ſome ſmall reſiſtance of the air) deſcend to the earth from equal heights in equal times; and that equality of times we may diſtinguiſh to a great accuracy, by the help of pendulums. Sir Iſaac Newton tried the thing in gold, ſilver, lead, glaſs, ſand, common ſalt, wood, water, and wheat. He provided two wooden boxes, round and equal, filled the one with wood, and ſuſpended an equal weight of gold in the centre of oſcillation of the other. The boxes hanging by equal threads of 11 feet, made a couple of pendulums, perfectly equal in weight and figure, and equally receiving the reſiſtance of the air. And placing the one by the other, he obſerved them to play together forwards and backwards, for a long time, with equal vibrations. And therefore the quantity of matter in the gold was to the quantity of matter in the wood, as the action of the motive force (or *vis motrix*) upon all the gold, to the action of the ſame upon all the wood; that is, as the weight of the one to the weight of the other. And the like happened in the other bodies. By theſe experiments, in bodies of the ſame weight, he could manifeſtly have diſcovered a difference of matter leſs than the thouſandth part of the whole, had any ſuch been. But, without all doubt, the nature of gravity towards the planets, is the ſame as towards the earth. For, ſhould we imagine our terreſtrial bodies removed to the orb of the moon, and there, together with the moon, deprived of all motion, to be let go, ſo as to fall together towards the earth; it is certain, from what we have demonſtrated before, that, in equal times, they would deſcribe equal ſpaces with the moon, and of conſequence are to the moon, in quantity of matter, as their weights to its weight. Moreover, ſince the ſatellites of Jupiter perform their revolutions in times which obſerve the ſeſquiplicate proportion of their diſtances from Jupiter's centre, their accelerative gravities towards Jupiter will be reciprocally as the ſquares of their diſtances from Jupiter's centre; that is, equal at equal diſtances. And therefore, theſe ſatellites, if ſuppoſed to fall towards Jupiter from equal heights, would deſcribe equal ſpaces in equal times, in like manner as heavy bodies do on our earth. And by the ſame argument, if the circumſolar planets were ſuppoſed to be let fall at equal diſtances from the ſun, they would, in their deſcent towards the ſun, deſcribe equal ſpaces in equal times. But forces, which equally accelerate unequal bodies, muſt be as thoſe bodies; that is to ſay, the weights of the planets towards the ſun muſt be as their quantities of matter. Further, that the weights of Jupiter and of his ſatellites towards the ſun are proportional to the ſeveral quantities of their matter, appears from the exceeding regular motions of the ſatellites. For if ſome of thoſe bodies were more ſtrongly attracted to the ſun in proportion to their quantity of matter than others, the motions of the ſatellites would be diſturbed by that inequality of attraction. If, at equal diſtances from the ſun, any ſatellite, in proportion to the quantity of its matter, did gravitate towards the ſun, with a force greater than Jupiter in proportion to his, according to any given proportion, ſuppoſe of *d* to *e;* then the diſtance between the centres of the ſun and of the ſatellite's orbit would be always greater than the diſtance between the centres of the ſun and of Jupiter, nearly in the ſubduplicate of that proportion. And if the ſatellite gravitated towards the ſun with a force, leſſer in the proportion of *e* to *d*, the diſtance of the centre of the ſatellite's orb from the ſun, would be leſs than the diſtance of the centre of Jupiter's from the ſun, in the ſubduplicate of the ſame proportion. Therefore, if, at equal diſtances from the ſun, the accelerative gravity of any ſatellite towards the ſun, were greater or leſs than the accelerating gravity of Jupiter towards the ſun, but by one $\frac{1}{1000}$ part of the whole gravity; the diſtance of the centre of the ſatellite's orbit from the ſun would be greater or leſs than the diſtance of Jupiter from the ſun, by one $\frac{1}{2000}$ part of the whole diſtance; that is, by a fifth part of the diſtance of the utmoſt ſatellite from the centre of Jupiter; an excentricity of the orbit, which would be very ſenſible. But the orbits of the ſatellites are concentric to Jupiter; therefore the accelerative gravities of Jupiter, and of all its ſatellites, towards the ſun, are equal among themſelves. And by the ſame argument, the weight of Saturn and of his ſatellites towards the ſun, at equal diſtances from the ſun, are as their ſeveral quantities of

of matter; and the weights of the moon and of the earth towards the fun, are either none, or accurately proportional to the maffes of matter which they contain.

But further, the weights of all the parts of every planet towards any other planet, are one to another as the matter in the feveral parts. For if fome parts gravitated more, others lefs, than for the quantity of their matter; then the whole planet, according to the fort of parts with which it moft abounds, would gravitate more or lefs, than in proportion to the quantity of matter in the whole. Nor is it of any moment whether thefe parts are external or internal. For if, for example, we fhould imagine the terreftrial bodies with us to be raifed up to the orb of the moon, to be there compared with its body; if the weights of fuch bodies were to the weights of the external parts of the moon, as the quantities of matter in the one and in the other refpectively; but to the weights of the internal parts, in a greater or lefs proportion; then likewife the weights of thofe bodies would be to the weight of the whole moon, in a greater or lefs proportion; againft what we have fhewed above.

Cor. 1. Hence the weights of bodies do not depend upon their forms and textures. For if the weights could be altered with the forms, they would be greater or lefs, according to the variety of forms in equal matter; altogether againft experience.

Cor. 2. Univerfally, all bodies about the earth gravitate towards the earth; and the weights of all, at equal diftances from the earth's centre, are as the quantities of matter which they feverally contain. This is the quality of all bodies within the reach of our experiments; and therefore (by rule 3.) to be affirmed of all bodies whatfoever. If the ether, or any other body, were either altogether void of gravity, or were to gravitate lefs in proportion to its quantity of matter; then, becaufe (according to Ariftotle, Des Cartes, and others) there is no difference betwixt that and other bodies, but in mere form of matter, by a fucceffive change from form to form, it might be changed at laft into a body of the fame condition with thofe which gravitate moft in proportion to their quantity of matter; and, on the other hand, the heavieft bodies, acquiring the firft form of that body, might by degrees quite lofe their gravity. And therefore the weights would depend upon the forms of bodies, and with thofe forms might be changed, contrary to what was proved in the preceding corollary.

Cor. 3. All fpaces are not equally full. For if all fpaces were equally full, then the fpecific gravity of the fluid which fills the region of the air, on account of the extreme denfity of the matter, would fall nothing fhort of the fpecific gravity of quick-filver, or gold, or any other the moft denfe body; and therefore, neither gold, nor any other body, could defcend in air. For bodies do not defcend in fluids, unlefs they are fpecifically heavier than the fluids. And if the quantity of matter in a given fpace can by any rarefaction be diminifhed, what fhould hinder a diminution to infinity?

Cor. 4. If all the folid particles of all bodies are of the fame denfity, nor can be rarefied without pores, a void fpace or vacuum muft be granted. [By bodies of the fame denfity, our author means thofe whofe *vires inertiæ* are in the proportion of their bulks.]

Prop. VI. That there is a power of gravity tending to all bodies, proportional to the feveral quantities of matter which they contain.

That all the planets mutually gravitate one towards another, we have proved before; as well as that the force of gravity towards every one of them, confidered apart, is reciprocally as the fquare of the diftance of places from the centre of the planet. And thence it follows, that the gravity tending towards all the planets, is proportional to the matter which they contain.

Moreover, fince all the parts of any planet *A* gravitate towards any other planet *B*; and the gravity of every part is to the gravity of the whole, as the matter of the part to the matter of the whole; and (by law 3.) to every action correfponds an equal re-action: therefore the planet *B* will, on the other hand, gravitate towards all the parts of the planet *A*; and its gravity towards any one part will be to the gravity towards the whole, as the matter of the part to the matter of the whole. *Q. E. D.*

Cor. 1. Therefore the force of gravity towards any whole planet, arifes from, and is compounded of, the forces of gravity towards all its parts. Magnetic and electric attractions afford us examples of this. For all attraction towards the whole arifes from the attractions towards the feveral parts. The thing may be eafily underftood in gravity, if we confider a greater planet as formed of a number of leffer planets, meeting together in one globe. For hence it would appear that the force of the whole muft arife from the forces of the component parts. If it be objected, That, according to this law, all bodies with us muft mutually gravitate one towards another, whereas no fuch gravitation any where appears; it is anfwered, That fince the gravitation towards thefe bodies is to the gravitation towards the whole earth, as thefe bodies are to the whole earth, the gravitation towards them muft be far lefs than to fall under the obfervation of our fenfes. [The experiments with regard to the attraction of mountains, however, have now further elucidated this point.]

Cor. 2. The force of gravity towards the feveral equal particles of any body, is reciprocally as the fquare of the diftance of places from the particles.

Prop. VII. In two fpheres mutually gravitating each towards the other, if the matter, in places on all fides round about and equidiftant from the centres, is fimilar; the weight of either fphere towards the other, will be reciprocally as the fquare of the diftance between their centres.

For the demonftration of this, fee the *Principia*, book i. prop. 75 and 76.

Cor. 1. Hence we may find and compare together the weights of bodies towards different planets. For the weights of bodies revolving in circles about planets, are as the diameters of the circles directly, and the fquares of their periodic times reciprocally; and their weights at the furfaces of the planets, or at any other diftances from their centres, are (by this prop.) greater or lefs, in the reciprocal duplicate proportion of the diftances. Thus from the periodic times of Venus, revolving about the fun, in $224^{d}.\ 16\frac{3}{4}^{h}$; of the utmoft circumjovial fatellite revolving about Jupiter, in $16^{d}.\ 16\frac{8}{15}^{h}$; of the Huygenian fatellite about Saturn in $15^{d}.\ 22\frac{2}{3}^{h}$; and of the moon about the earth in $27^{d}.\ 7^{h}$.

Newtonian Philosophy

$7^h. 43'$; compared with the mean diftance of Venus from the fun, and with the greateft heliocentric elongations of the outmoft circumjovial fatellite from Jupiter's centre, $8' 16''$; of the Huygenian fatellite from the centre of Saturn, $3' 4''$; and of the moon from the earth, $10' 33''$; by computation our author found, that the weight of equal bodies, at equal diftances from the centres of the fun, of Jupiter, of Saturn, and of the earth, towards the fun, Jupiter, Saturn, and the earth, were one to another, as $\frac{1}{1067}$, $\frac{1}{3021}$, and $\frac{1}{169282}$ refpectively. Then, becaufe, as the diftances are increafed or diminifhed, the weights are diminifhed or increafed in a duplicate ratio; the weights of equal bodies towards the fun, Jupiter, Saturn, and the earth, at the diftances 10000, 997, 791, and 109, from their centres, that is, at their very fuperficies, will be as 10000, 943, 529, and 435 refpectively.

Cor. 2. Hence likewife we difcover the quantity of matter in the feveral planets. For their quantities of matter are as the forces of gravity at equal diftances from their centres, that is, in the fun, Jupiter, Saturn, and the earth, as 1, $\frac{1}{1067}$, $\frac{1}{3021}$, and $\frac{1}{169282}$ refpectively. If the parallax of the fun be taken greater or lefs than $10'' 30'''$, the quantity of matter in the earth muft be augmented or diminifhed in the triplicate of that proportion.

Cor. III. Hence alfo we find the denfities of the planets. For (by prop. 72. book 1.) the weights of equal and fimilar bodies towards fimilar fpheres, are, at the furfaces of thofe fpheres, as the diameters of the fpheres. And therefore the denfities of diffimilar fpheres are as thofe weights applied to the diameters of the fpheres. But the true diameters of the fun, Jupiter, Saturn, and the earth, were one to another as 10000, 997, 791, and 109; and the weights towards the fame, as 10000, 943, 529, and 435 refpectively; and therefore their denfities are as 100, $94\frac{1}{2}$, 67, and 400. The denfity of the earth, which comes out by this computation, does not depend upon the parallax of the fun, but is determined by the parallax of the moon, and therefore is here truly defined. The fun therefore is a little denfer than Jupiter, and Jupiter than Saturn, and the earth four times denfer than the fun; for the fun, by its great heat, is kept in a fort of a rarefied ftate. The moon is denfer than the earth.

Cor. 4. The fmaller the planets are, they are, *cæteris paribus*, of fo much the greater denfity. For fo the powers of gravity on their feveral furfaces come nearer to equality. They are likewife, *cæteris paribus*, of the greater denfity as they are nearer to the fun. So Jupiter is more denfe than Saturn, and the earth than Jupiter. For the planets were to be placed at different diftances from the fun, that, according to their degrees of denfity, they might enjoy a greater or lefs proportion of the fun's heat. Our water, if it were removed as far as the orb of Saturn, would be converted into ice, and in the orb of Mercury would quickly fly away in vapour. For the light of the fun, to which its heat is proportional, is feven times denfer in the orb of Mercury than with us: and by the thermometer Sir Ifaac found, that a fevenfold heat of our fummer-fun will make water boil. Nor are we to doubt, that the matter of Mercury is adapted to its heat, and is therefore more denfe than the matter of our earth; fince, in a denfer matter, the operations of nature require a ftronger heat.

It is fhewn in the fcholium of prop. 22. book 2. of the *Principia*, that at the height of 200 miles above the earth, the air is more rare than it is at the fuperficies of the earth, in the ratio of 30 to 0,0000000000003998, or as 75000000000000 to 1 nearly. And hence the planet Jupiter, revolving in a medium of the fame denfity with that fuperior air, would not lofe by the refiftance of the medium the 1000000th part of its motion in 1000000 years. In the fpaces near the earth, the refiftance is produced only by the air, exhalations, and vapours. When thefe are carefully exhaufted by the air-pump from under the receiver, heavy bodies fall within the receiver with perfect freedom, and without the leaft fenfible refiftance; gold itfelf, and the lighteft down, let fall together, will defcend with equal velocity; and though they fall through a fpace of four, fix, and eight feet, they will come to the bottom at the fame time; as appears from experiments. And therefore the celeftial regions being perfectly void of air and exhalations, the planets and comets meeting no fenfible refiftance in thofe fpaces, will continue their motions through them for an immenfe fpace of time.

Niagara.

NIAGARA, a fort of North America taken from the French during the laft war, which in a manner commands all the interior parts of the continent, and is a key to the whole of North America. It is fituated on the lake Ontario; and about fix leagues from it is the greateft cataract in the world, known by the name of the *water-fall of Niagara*. The river at this fall runs from S. S. E. to N. N. W. and the rock of the fall croffes it not in a right line, but forming a kind of figure like an hollow femicircle or horfefhoe. Above the fall, in the middle of the river, is an ifland about 800 or 1000 feet long; the lower end of which is juft at the perpendicular edge of the fall. On both fides of this ifland runs all the water that comes from the lakes of Canada; viz. Lake Superior, Lake Mifchigan, Lake Huron, and Lake Eric, which have fome large rivers that open themfelves into them. Before the water comes to this ifland, it runs but flowly compared with its motion afterwards, when it grows the moft rapid in the world, running with a furprifing fwiftnefs before it comes to the fall. It is perfectly white, and in many places is thrown high up into the air. The water that runs down on the weft fide is more rapid, in greater abundance, and whiter, than that on the eaft fide; and feems almoft to outfly an arrow in fwiftnefs. When you are at the fall, and look up the river, you may fee that the water is every where exceedingly fteep, almoft like the fide of an hill; but when you come to look at the fall itfelf, it is impoffible to exprefs the amazement it occafions. The height of it, as meafured by mathematical inftruments, is found to be exactly 137 feet; and when the water is come to the bottom, it jumps back to a very great height in the air. The noife may be heard at the diftance of 45 miles, but feldom further; nor can it be heard even at Fort Niagara, which is only fix leagues diftant, unlefs Lake Ontario is calm. At that fort it is obferved, that when they hear the noife of the fall more loud than ordinary, they are fure that a north-eaft wind will follow; which is the more fur-

Niagara. prifing, as the fort lies fouth-weft from the fall. At fome times the fall makes a much greater noife than at others; and this is held for an infallible fign of approaching rain or other bad weather.

From the place where the water falls there arifes abundance of vapour like very thick fmoke, infomuch that when viewed at a diftance you would think that the Indians had fet the forefts on fire. Thefe vapours rife high in the air when it is calm, but are difperfed by the wind when it blows hard. If you go into this vapour or fog, or if the wind blows it on you, it is fo penetrating, that a few moments you will be as wet as if you had been nnder water. Some are of opinion, that when birds come flying into this fog or fmoke of the fall, they drop down and perifh in the water; either becaufe their wings are become wet, or that the noife of the fall aftonifhes them, and they know not where to go in the darknefs: but others think that feldom or never any bird perifhes there in that manner; becaufe, among the abundance of birds found dead below the fall, there are no other forts than fuch as live and fwim frequently in the water; as fwans, geefe, ducks, water-hens, teal, and the like. And very often great flocks of them are feen going to deftruction in this manner: they fwim in the river above the fall, and fo are carried down lower and lower by the water; and as water-fowl commonly take great delight in being carried with the ftream, they indulge themfelves in enjoying this pleafure fo long, till the fwiftnefs of the water becomes fo great, that it is no longer poffible for them to rife, but they are driven down the precipice, and perifh. They are obferved, when they draw nigh the fall, to endeavour with all their might to take wing and leave the water; but they cannot. In the months of September and October fuch abundant quantities of dead water-fowl are found every morning below the fall, on the fhore, that the garrifon of the fort for a long time live chiefly upon them. Befides the fowl, they find alfo feveral forts of dead fifh, alfo deer, bears, and other animals which have tried to crofs the water above the fall; the larger animals are generally found broken to pieces. Juft below, a little way from the fall, the water is not rapid, but goes all in circles, and whirls like a boiling pot; which however does not hinder the Indians going upon it in fmall canoes a-fifhing; but a little further, and lower, the other fmaller falls begin. When you are above the fall, and look down, your head begins to turn; even fnch as have been here numberlefs times, will feldom venture to look down, without at the fame time keeping faft hold of fome tree with one hand.

It was formerly thought impoffible for any body living to come at the ifland that is in the middle of the fall: but an accident that happened 34 years ago, or thereabouts, made it appear otherwife. The hiftory is this: Two Indians of the Six Nations went out from Niagara fort to hunt upon an ifland that is in the middle of the river, or ftrait, above the great fall, on which there ufed to be abundance of deer. They took fome French brandy with them from the fort, which they tafted feveral times as they were going over the carrying-place; and when they were in their canoe, they took now and then a dram, and fo went along up the ftrait towards the ifland where they propofed to hunt; but growing fleepy, they laid themfelves down in the canoe, which getting loofe drove back with the ftream, farther and farther down, till it came nigh that ifland that is in the middle of the fall. Here one of them, awakened by the noife of the fall, cries out to the other, that they were gone: Yet they tried if poffible to fave life. This ifland was nigheft, and with much working they got on fhore their. At firft they were glad; but when they had confidered every thing, they thought themfelves hardly in a better ftate than if they had gone down the fall, fince they had now no other choice, than either to throw themfelves down the fame, or perifh with hunger. But hard neceffity put them on invention. At the lower end of the ifland the rock is perpendicular, and no water is running there. The ifland has plenty of wood; they went to work then, and made a ladder or fhrouds of the bark of the lind-tree (which is very tough and ftrong) fo long till they could with it reach the water below; onc end of this bark-ladder they tied faft to a great tree that grew at the fide of the rock above the fall, and let the other end down to the water. So they went down along their new-invented ftairs, and when they came to the bottom in the middle of the fall they refted a little; and as the water next below the fall is not rapid, as before-mentioned, they threw themfelves out into it, thinking to fwim on fhore. We have faid before, that one part of the fall is on one fide of the ifland, the other on the other fide. Hence it is, that the waters of the two cataracts running againft each other, turn back againft the rock that is juft under the ifland. Therefore, hardly had the Indians begun to fwim, before the waves of the eddy threw them down with violence againft the rock from whence they came. They tired it feveral times, but at laft grew weary; and by being often thrown againft the rock they were much bruifed, and the fkin torn off their bodies in many places. So they were obliged to climb up ftairs again to the ifland, not knowing what to do. After fome time they perceived Indians on the fhore, to whom they cried out. Thefe faw and pitied them, but gave them little hope or help: yet they made hafte down to the fort, and told the commandant where two of their brothers were. He perfuaded them to try all poffible means of relieving the two poor Indians; and it was done in the following manner.

The water that runs on the eaft fide of this ifland is fhallow, efpecially a little above the ifland towards the eaftern fhore. The commandant caufed poles to be made and pointed with iron; two Indians took upon them to walk to this ifland by the help of thefe poles, to fave the other poor creatures, or perifh themfelves. They took leave of all their friends, as if they were going to death. Each had two fuch poles in his hands, to fet to the bottom of the ftream, to keep them fteady. So they went and got to the ifland, and having given poles to the two poor Indians there, they all returned fafely to the main. Thefe two Indians who in the abovementioned manner were firft brought to this ifland were nine days on the ifland, and almoft ready to ftarve to death. Now fince the road to this ifland has been found, the Indians go there often to kill deer, which have tried to crofs the river above the fall, and are driven upon the ifland by the ftream. On the

the weſt ſide of this iſland are ſome ſmall iſlands or rocks, of no conſequence. The eaſt ſide of the river is almoſt perpendicular, the weſt ſide more ſloping. In former times a part of the rock at the fall which is on the weſt ſide of the iſland, hung over in ſuch a manner, that the water which fell perpendicularly from it, left a vacancy below, ſo that people could go under between the rock and the water; but the prominent part ſome years ſince broke off and fell down. The breadth of the fall, as it runs in a ſemi-circle, is reckoned to be about 300 feet. The iſland is in the middle of the fall, and from it on each ſide is almoſt the ſame breadth; the breadth of the iſland at its lower end is about 100 feet. Below the fall, in the holes of the rocks, are great plenty of eels, which the Indians and French catch with their hands without any other means. Every day when the ſun ſhines, you ſee here from ten o'clock in the morning to two in the afternoon, below the fall, and under you, where you ſtand at the ſide of the fall, a glorious rainbow, and ſometimes two, one within the other. The more vapours, the brighter and clearer is the rainbow. When the wind carries the vapours from that place, the rainbow is gone, but appears again as ſoon as new vapours come. From the fall to the landing above it, where the canoes from Lake Erie put aſhore (or from the fall to the upper end of the carrying-place) is half a mile. Lower the canoes dare not come, leſt they ſhould be obliged to try the fate of the two Indians, and perhaps with leſs ſucceſs. They have often found below the fall pieces of human bodies, perhaps drunken Indians, that have unhappily come down to the fall. The French ſay, that they have often thrown whole great trees into the water above, to ſee them tumble down the fall: they went down with ſurpriſing ſwiftneſs, but could never be ſeen afterwards; whence it was thought there was a bottomleſs deep or abyſs juſt under the fall. The rock of the fall conſiſts of a grey limeſtone.

NICÆA, (anc. geogr.), the metropolis of Bithynia; ſituate on the lake Aſcanius, in a large and fertile plain; in compaſs 16 ſtadia: firſt built by Antigonus, the ſon of Philip, and thence called *Antigonea;* afterwards completed by Lyſimachus, who called it *Nicæa*, after his conſort the daughter of Antipater. According to Stephanus, it was originally a colony of the Bottiæi, a people of Thrace, and called *Ancore;* and afterwards called *Nicæa*. Now *Nice* in Aſia the Leſs. Famous for the firſt general council.—A ſecond *Nicæa*, (Diodorus Siculus,) of Corſica.—A third, of the Hither India, (Arrian); ſituate on the weſt ſide of the Hydaſpes, oppoſite to Buciphale, on the eaſt ſide.—A fourth *Nicæa*, a town of Liguria, at the Maritime Alps, on the eaſt ſide of the river Paulon near its mouth, which runs between the Varus and Nicæa, (Mela). A colony of the Maſſilians, (Stephanus); the laſt town of Italy to the weſt. Now *Nizza* or *Nice*, capital of the county of that name, on the Mediterranean.—A fifth, of Locris, (Strabo); a town near Thermopylæ; one of the keys of that paſs. It ſtood on the Sinus Maliacus.

NICANDER *of* COLOPHON, a celebrated grammarian, poet, and phyſician, who lived about the 160th Olympiad, 140 years before Chriſt, in the reign of Attalus king of Pergamus, who overcame the Gallo-Greeks. He lived many years in Etolia, of which country he wrote a hiſtory. He wrote alſo many other works, of which only two are now remaining. The one is intitled *Theriaca*, deſcribing in verſe the accidents attending wounds made by venomous beaſts, with the proper remedies; the other bearing the title of *Alexipharmaca*, wherein he treats poetically of poiſons and their antidotes. This Nicander is not to be confounded with Nicander of Thyatira.

NICARAGUA, a large river of South America, in a province of the ſame name, whoſe weſtern extremity lies within 5 miles of the South Sea. It is full of dreadful cataracts, and falls at length into the North Sea.

NICARAGUA, a maritime province of South America, in Mexico, bounded on the north by Honduras, on the eaſt by the North Sea, on the ſouth-eaſt by Coſta Rica, and on the ſouth-weſt by the South Sea; being 400 miles in length from eaſt to weſt, and 120 in breadth from north to ſouth. It is one of the moſt fruitful and agreeable provinces in Mexico, and is well watered with lakes and rivers. The air is wholeſome and temperate; and this country produces plenty of ſugar, cochineal, and fine chocolate. One of the lakes is 200 miles in circumference, has an iſland in the middle, and, as ſome ſay, has a tide. Leon de Nicaragua is the capital town.

NICARIA, an iſland of the Archipelago, between Samos and Tine, about 50 miles in circumference. A chain of high mountains run thro' the middle, covered with wood, and ſupply the country with ſprings. The inhabitants are very poor, and of the Greek communion; however, they have a little wheat, and a good deal of barley, figs, honey, and wax.

NICASTRO, an epiſcopal town of Italy, in the kingdom of Naples, and in the Farther Calabria; 16 miles ſouth of Coſenza. E. Long. 15. 59. N. Lat. 39. 15.

NICE, an ancient, handſome, and conſiderable town on the confines of France and Italy, and capital of a county of the ſame name, with a ſtrong citadel, a biſhop's ſee, and a ſenate, which is a kind of a democracy. It has been ſeveral times taken by the French, and laſt of all in 1744, but rendered back after the treaty of Aix-la-Chapelle. It is very agreeably ſituated, four miles from the mouth of the river Var, 83 miles S. by W. of Turin, and 83 eaſt of Aix. E. Long. 6. 22. N. Lat. 43. 42.

NICE, a county and province in the dominions of the duke of Savoy, bounded on the eaſt by the territory of Genoa and Proper Piedmont, on the north by the marquiſate of Saluces and Dauphiny, on the weſt by Provence and the Mediterranean ſea, and on the ſouth by the principality of Monaco. The inhabitants ſupply Genoa with a great deal of timber for building ſhips; and carry on a great trade in linen-cloth, paper, oil, wine, and honey. Nice is the capital town.

NICE, an ancient town of Aſia, in Natolia, now called *Iſnick*, with a Greek archbiſhop's ſee. It is famous for the general council aſſembled here in 325, who endeavoured to ſuppreſs the doctrines of Arius. It was formerly a large, populous, and well-built place, and now is not inconſiderable. See ISNIC.

NICEPHORUS (Gregorius), a Greek hiftorian in the 14th century, was librarian to the church of Conftantinople, and had a great fhare in the tranfactions of his time. He wrote a hiftory, which extends from the year 1204 to 1341. The beft edition of this work is that of the Louvre, in Greek and Latin, in 1702.

NICEPHORUS (Califtus), a Greek hiftorian, who flourifhed in the 14th century under the emperor Andronicus Paleologus the elder, wrote an ecclefiaftical hiftory in 23 books; 18 of which are ftill extant, containing the tranfactions of the church from the birth of Chrift to the death of the emperor Phocas in 610. We have nothing elfe but the arguments of the other five books from the commencement of the reign of the emperor Heraclius to the end of that of Leo the philofopher, who died in the year 911. Nicephorus dedicated his hiftory to Andronicus Paleologus the Elder. It was tranflated into Latin by John Langius; and has gone through feveral editions, the beft of which is that of Paris in 1630.

NICERON (John Francis), an ingenious minim, born at Paris in 1613, who diftinguifhed himfelf by his knowledge in Optics, concerning which he wrote fome treatifes, though he died at the age of 33.

NICERON (John Peter), was born at Paris, of an ancient and noble family, in the year 1685. He entered young into the order of Barnabites, and was profeffor of rhetoric and philofophy in the college of Montargis. He is fufficiently known for conducting the "Memoirs of men illuftrious in the republic of letters," of which he publifhed 39 volumes. He alfo tranflated fome Englifh works into French.

NICETAS (David), a Greek hiftorian, a native, as fome relate, of Paphlagonia, who lived about the end of the 9th century. He wrote, The life of St Ignatius, patriarch of Conftantinople; which was tranflated into Latin by Frederic Mutius bifhop of Termoli: he compofed alfo feveral panegyrics in honour of the apoftles and other faints, which are inferted in the laft continuation of the *Bibliotheca Patrum* by Combefis.

NICETAS (furnamed SERRON), deacon of the church of Conftantinople, cotemporary with Theophylact in the 11th century, and afterwards bifhop of Heraclea, wrote a Catena upon the book of Job, compiled from paffages of feveral of the fathers, which was printed at London in folio, 1637. We have alfo, by the fame writer, feveral *catenæ* upon the Pfalms and Canticles, Bafil 1552; together with a Commentary on the poems of Gregory Nazianzen.

NICETAS (Arhominatis), a Greek hiftorian of the 13th century, called *Coniates*, as being born at Chone, or Coloffus, in Phrygia. He was employed in feveral confiderable affars at the court of Conftant'nople; and when that city was taken by the French in 1204, he withdrew with a young girl taken from the enemy, to Nice in Bithynia, where he married his captive, and died in 1206. He wrote a Hiftory, or Annals, from the death of Alexius Comnenus in the year 1118, to that of Badouin in 1205: of which work we have a Latin tranflation by Jerome Wolfius, printed at Bafil in 1557; and it has been inferted in the body of the Byzantine Hiftorians, printed in France at the Louvre.

NICHE, in architecture, a hollow funk into a wall, for the commodious and agreeable placing of a ftatue. The word comes from the Italian *nechia*, "fea-fhell;" in regard the ftatue is here inclofed in a fhell, or perhaps on account of the fhell wherewith the tops of fome of them are adorned.

NICIAS, a celebrated painter of Athens, flourifhed about 322 years before the Chriftian æra; and was univerfally extolled for the great variety and noble choice of his fubjects, the force and relievo of his figures, his fkill in the diftribution of the lights and fhadows, and his dexterity in reprefenting all forts of four-footed animals, beyond any mafter of his time. His moft celebrated piece was that of Tartarus or Hell, as it is defcribed by Homer, for which king Ptolemy the fon of Lagus offered him 60 talents, or 11,250l. which he refufed, and generoufly prefented it to his own country. He was likewife much efteemed by all his cotemporaries, for his excellent talent in fculpture.

NICKEL, a femi-metal, firft defcribed by Mr Cronftedt in the Swedifh Memoirs for the years 1751 and 1754. The properties there attributed to it are, 1. That it is of a white colour, inclining to red. 2. Its texture is folid, and fhining in its fractures. 3. Its fpecific gravity is to that of water as 8500 to 1000. 4. It is confiderably fixed in the fire. 5. It is calcinable, and its calx is green. 6. This calx is not very fufible; but it neverthelefs tinges glafs of a tranfparent reddifh brown, or jacinth colour. 7. It diffolves in aquafortis, aqua regia, and marine acid, but difficultly in vitriolic acid. All thefe folutions have a deep-green colour. The vitriol formed of it is alfo of the fame colour; and the colcothar of this vitriol, and alfo the precipitates from the folutions, are rendered by calcination of a light-green colour. 8. Thefe precipitates are foluble by fpirit of fal ammoniac, and the folution has a blue colour. But no copper can be produced by a reduction of the precipitates. 9. It ftrongly attracts fulphur. 10. It unites with all metallic fubftances, excepting filver, quickfilver, and zinc. Its attraction to regulus of cobalt is the ftrongeft, next to which is that to iron, and then to arfenic. 11. It retains its phlogifton a long time in the fire, and its calx is reducible by a very fmall quantity of inflammable matter. It requires, however, a ftrong red heat before it can be fufed, and melts a little fooner, or as foon as gold or copper. Nickel is contained in the reddifh-yellow mineral, called *Kupfer-nickel*, which, befides nickel, contains alfo iron, regulus of cobalt, arfenic, and fulphur.

NICOBAR ISLANDS, the name of feveral iflands in Afia, lying at the entrance of the gulph of Bengal. The largeft of thefe iflands is about 40 miles long and 15 broad, and the inhabitants are faid to be a harmlefs fort of people, ready to fupply the fhips that ftop there with provifions.

NICOLAITANS, in church-hiftory, Chriftian heretics who affumed this name from Nicholas of Antioch; who, being a Gentile by birth, firft embraced Judaifm, and then Chriftianity; when his zeal and devotion recommended him to the church of Jerufalem, by whom he was chofen one of the firft deacons. Many of the primitive writers believe that Nicholas

cholas was rather the occafion than the author of the infamous practices of thofe who affumed his name, who were exprefsly condemned by the Spirit of God himfelf, Rev. ii. 6. And indeed their opinions and actions were highly extravagant and criminal. They allowed a community of wives, and made no diftinction between ordinary meats and thofe offered to idols. According to Eufebius, they fubfifted but a fhort time; but Tertullian fays that they only changed their name, and that their herefies paffed into the fect of the Cainians.

NICOLAS (St), an ifland of the Atlantic Ocean, and one of the moft confide.able of thofe of Cape Verde, lying between Santa Lucia and St Jago. It is of a triangular figure, and about 75 miles in length. The land is ftony, mountainous, and barren; but there are a great many goats in a valley inhabited by the Portuguefe. W. Long. 33. 35. N. Lat. 17. 0.

NICOLE (Peter), one of the fineft writers in Europe, was born at Chartres in 1625, of a confpicuous family. He adhered to the Janfenifts; and joined in the compofition of feveral works with Mr Arnauld, whofe faithful companion he was during the 10 or 12 years of his retirement. He gave a Latin tranflation of Pafcal's *Provinciales*, and added a commentary to them. One of his fineft works is his *Effais de Morale*. He wrote very fubtilely againft the Proteftants. His treatife on the unity of the church is efteemed a mafterly piece. He died at Paris in 1695, a few days after the publication of his treatife concerning the Quietifts. He was greatly fkilled in polite literature. To him is afcribed a collection of Latin epigrams, and of Greek, Spanifh, and Italian fentences, which has borne feveral impreffions, and has a learned preface to it.

NICOLO (St), the moft confiderable, ftrongeft, and beft peopled of the ifles of Tremeti in the gulf of Venice, to the eaft of St Domino, and to the fouth of Capparata. It has a harbour defended by feveral towers; and a fortrefs, in which is an abbey, with a very handfome church. E. Long. 15. 37. N. Lat. 42. 7.

NICOMEDES, the name of feveral kings of the ancient Bithynia. See BITHYNIA.

NICOMEDIA (anc. geogr.), metropolis of Bithynia, built by Nicomedes the grandfather of Prufias. Situated on a point of the Sinus Aftacenus, (Pliny); furnamed the *Beautiful*, (Athenæus): the largeft city of Bithynia, (Paufanias), who fays it was formerly called *Aftacus;* though Pliny diftinguifhes Aftacum and Nicomedia as different cities. Nicomedia was very famous, not only under its own kings, but under the Romans: the royal refidence of Dioclefian, and of Conftantine while Conftantinople was building, if we may credit Nicephorus. It is ftill called *Nicomedia*, at the bottom of a bay of the Propontis in the Hither Afia. E. Long. 30. 0. N. Lat. 41. 20. It is a place of confequence; carries on a trade in filk, cotton, glafs, and earthen-ware, and is the fee of a Greek archbifhop.

NICOPOLI, a town of Turkey in Europe, and in Bulgaria, famous for being the place where the firft battle was fought between the Turks and Chriftians in 1396; and where the latter were defeated with the lofs of 20,000 men. E. Long. 25. 33. N. Lat. 43. 46.

NICOSIA, the capital of the ifland of Cyprus, where a Turkifh bafhaw refides. It is delightfully fituated between the mountains of Olympus, and a chain of others; and was formerly well fortified by the Venetians; but the works are now in ruins. E. Long. 33. 35. N. Lat. 35. 1.

NICOT (John), lord of Vilemain, and mafter of requefts of the French king's houfehold, was born at Nifmes, and was fent ambaffador to Portugal in 1559; whence he brought the plant which, from his name, was called *Nicotiana*, but is now more known by the name of *tobacco*. He died at Paris in 1603. He wrote a French and Latin dictionary in folio; a treatife on navigation; and other works.

NICOTIANA, TOBACCO; a genus of the monogynia order, belonging to the pentandria clafs of plants. There are feven fpecies, of which the moft remarkable is the tabacum, or common tobacco-plant. This was firft difcovered in America by the Spaniards about the year 1560, and by them imported into Europe. It had been ufed by the inhabitants of America long before; and was called by thofe of the iflands *yoli*, and *pætun* by the inhabitants of the continent. It was fent into Spain from Tabaco, a province of Yucatan, where it was firft difcovered, and from whence it takes its common name. Sir Walter Raleigh firft introduced it into England about the year 1585, and was the firft who taught them how to fmoke it. Tobacco is commonly ufed among the oriental nations, though it is uncertain by whom it was introduced among them. Confiderable quantities of it are cultivated in the Levant, on the coafts of Greece and the Archipelago, in Italy, and in the ifland of Malta.

There are two varieties of that fpecies of Nicotiana which is cultivated for common ufe, and which are diftinguifhed by the names of *Oronokoe*, and *fweet-fcented tobacco*. They differ from each other only in the figure of their leaves; thofe of the former being longer and narrower than the latter. They are tall herbaceous plants, growing erect with fine foliage, and rifing with a ftrong ftem from fix to nine feet high. The ftalk, near the root, is upwards of an inch diameter, and furrounded with a kind of hairy or velvet clammy fubftance, of a yellowifh-green colour. The leaves are rather of a deeper green, and grow alternately at the diftance of two or three inches from each other. They are oblong, of a fpear-fhaped oval, and fimple; the largeft about 20 inches long, but decreafing in fize as they afcend, till they come to be only 10 inches long, and about half as broad. The face of the leaves is much corrugated, like thofe of fpinage when full ripe. Before they come to maturity, when they are about five or fix inches long, the leaves are generally of a full green, and rather fmooth; but as they increafe in fize, they become rougher, and acquire a yellowifh caft. The ftem and branches are terminated by large bunches of flowers collected into clufters, of a delicate red; the edges, when full-blown, inclining to a pale purple. They continue in fucceffion till the end of the fummer; when they are fucceeded by feeds of a brown colour, and kidney-fhaped. Thefe are very fmall, each capfule containing about 1000; and the

the whole produce of a ſingle plant is reckoned at about 350,000. The ſeeds ripen in the month of September.

Mr Carver informs us, that the Oronokoe, or, as it is called, the *long Virginia tobacco*, is the kind beſt ſuited for bearing the rigour of a northern climate, the ſtrength as well as the ſcent of the leaves being greater than that of the other. The *ſweet-ſcented* ſort flouriſhes moſt in a ſandy ſoil, and in a warm climate, where it greatly exceeds the former in the celerity of its growth; and is likewiſe, as its name intimates, much more mild and pleaſant.

Tobacco thrives beſt in a warm, kindly, rich ſoil, that is not ſubject to be over-run by weeds. In Virginia, the ſoil in which it thrives beſt is warm, light, and inclining to be ſandy; and therefore, if the plant is to be cultivated in Britain, it ought to be planted in a ſoil as nearly of the ſame kind as poſſible. Other kinds of ſoils might probably be brought to ſuit it, by a mixture of proper manure; but we muſt remember, that whatever manure is made uſe of muſt be thoroughly incorporated with the ſoil. The beſt ſituation for a tobacco plantation is the ſouthern declivity of a hill rather gradual than abrupt, or a ſpot that is ſheltered from the north winds: but at the ſame time it is neceſſary that the plants enjoy a free air; for without that they will not proſper.

As tobacco is an annual plant, thoſe who intend to cultivate it ought to be as careful as poſſible in the choice of the ſeeds; in which, however, with all their care, they may be ſometimes deceived. The ſeeds are to be ſown about the middle of April, or rather ſooner in a forward ſeaſon, in a bed prepared for this purpoſe of ſuch ſoil as hath been already deſcribed, mixed with ſome warm rich manure. In a cold ſpring, hot-beds are moſt eligible for this purpoſe, and gardeners imagine that they are always neceſſary: but Mr Carver tells us, that he is convinced, when the weather is not very ſevere, the tobacco-ſeeds may be raiſed without doors; and for this purpoſe gives us the following directions.

Treatiſe on the culture of Tobacco.

"Having ſown the feed in the manner above directed, on the leaſt apprehenſion of a froſt after the plants appear, it will be neceſſary to ſpread mats over the beds, a little elevated from the ground by poles laid acroſs, that they may not be cruſhed. Theſe, however, muſt be removed in the morning ſoon after the ſun appears, that they may receive as much benefit as poſſible from its warmth, and from the air. In this manner proceed till the leaves have attained about two inches in length, and one in breadth; which they will do in about a month after they are ſown, or near the middle of May, when the froſts are uſually at an end. One invariable rule for their being able to bear removal is, when the fourth leaf is ſprouted, and the fifth juſt appears. Then take the opportunity of the firſt rains or gentle ſhowers to tranſplant them into ſuch a ſoil and ſituation as before deſcribed; which muſt be done in the following manner.—The land muſt be ploughed, or dug up with ſpades, and made as mellow and light as poſſible. Where the plants are to be placed, raiſe with the hoe ſmall hillocks at the diſtance of two feet or a little more from each other, taking care that no hard ſods or lumps are in it; and then juſt indent the middle of each, without drilling holes, as for ſome other plants.

"When your ground is thus prepared, dig in a gentle manner from their native bed ſuch plants as have attained the proper growth for tranſplanting abovementioned; and drop, as you paſs, one on every hillock. Inſert a plant gently into each centre, preſſing the ſoil around it gently with your fingers; and taking the greateſt care, during the operation, that you do not break off any of the leaves, which are at this time exquiſitely tender. If the weather proves dry after they are thus tranſplanted, they muſt be watered with ſoft water, in the ſame manner as is uſually done to coleworts, or plants of a ſimilar kind. But though you now ſeem to have a ſufficient quantity of plants for the ſpace you intend to cultivate, it is yet neceſſary that you continue to attend to your bed of ſeedlings, that you may have enough to ſupply any deficiencies which through accident may ariſe. From this time great care muſt be taken to keep the ground ſoft and free from weeds, by often ſtirring with your hoe the mould round the roots; and to prune off the dead leaves that ſometimes are found near the bottom of the ſtalk.

"The difference of this climate from that in which I have been accuſtomed to obſerve the progreſs of this plant, will not permit me to direct with certainty the time which is moſt proper to take off the top of it, to prevent it from running to ſeed. This knowledge can only be acquired by experience. When it has riſen to the height of more than two feet, it commonly begins to put forth the branches on which the flowers and ſeeds are produced; but as this expanſion, if ſuffered to take place, would drain the nutriment from the leaves, which are the moſt valuable part, and thereby leſſen their ſize and efficacy, it becomes needful at this ſtage to nip off the extremity of the ſtalk to prevent its growing higher. In ſome other climates, the top is commonly cut off when the plant has 15 leaves; but if the tobacco is intended to be a little ſtronger than uſual, this is done when it has only 13; and ſometimes, when it is deſigned to be remarkably powerful, 11 or 12 are only allowed to expand. On the contrary, if the planter is deſirous of having his crop very mild, he ſuffers it to put forth 18 or 20: but in this calculation, the three or four lower leaves next the ground, which do not grow ſo large and fine as the others, are not to be reckoned.

"This operation, denominated *topping* the tobacco, is much better performed by the finger and thumb than with any inſtrument; becauſe the graſp of the fingers cloſes the pores of the plant; whereas, when it is done by inſtruments, the juices are in ſome degree exhauſted. Care muſt alſo be taken to nip off the ſprouts that will be continually ſpringing up at the junction of the leaves with the ſtalks. This is termed *ſuccouring*, or *ſuckering*, the tobacco; and ought to be repeated as often as occaſion requires.

"As it is impoſſible to aſcertain the due time for topping the plant, ſo it is equally impoſſible, without experiment, to aſcertain the time it will take to ripen in this country. The apparent ſigns of its maturity are theſe: The leaves, as they approach a ſtate of ripeneſs, become more corrugated or rough; and when fully ripe, appear mottled with yellowiſh ſpots on the raiſed parts; whilſt the cavities retain their uſual green colour.

They

Nicotiana. They are at this time alſo thicker than they have before been; and are covered with a downy velvet, like that formerly mentioned, on the ſtalks. If heavy rains happen at this critical period, they will waſh off this excreſcent ſubſtance, and thereby damage the plants. In this caſe, if the froſty nights are not begun, it is proper to let them ſtand a few days longer; when, if the weather be moderate, they will recover this ſubſtance again. But if a froſt unexpectedly happens during the night, they muſt be carefully examined in the morning, before the ſun has any influence upon them; and thoſe which are found to be covered with froſty particles, whether thoroughly ripe or not, muſt be cut up; for though they may not all appear to be arrived at a ſtate of maturity, yet they cannot be far from it, and will differ but little in goodneſs from thoſe that are perfectly ſo."

Tobacco is ſubject to be deſtroyed by a worm; and without proper care to exterminate this enemy, a whole field of plants may ſoon be loſt. This animal is of the horned ſpecies, and appears to be peculiar to the tobacco-plant; ſo that in many parts of America it is diſtinguiſhed by the name of the *tobacco-worm*. In what manner it is firſt produced, or how propagated, is unknown: but it is not diſcernible till the plants have attained about half their height; and then appears to be nearly as large as a gnat. Soon after this it lengthens into a worm; and by degrees increaſes in magnitude to the bigneſs of a man's finger. In ſhape it is regular from its head to its tail, without any diminution at either extremity. It is indented or ribbed round at equal diſtances, nearly a quarter of an inch from each other; and having at every one of theſe diviſions a pair of feet or claws, by which it faſtens itſelf to the plant. Its mouth, like that of the caterpillar, is placed under the fore-part of the head. On the top of the head, between the eyes, grows a horn about half an inch long, and greatly reſembling a thorn; the extreme part of which is of a brown colour, a firm texture, and the extremity ſharp-pointed. It is eaſily cruſhed; being only, to appearance, a collection of green juice incloſed in a membranaceous covering, without the internal parts of an animated being. The colour of its ſkin is in general green, interſperſed with ſeveral ſpots of a yellowiſh white; and the whole covered with a ſhort hair ſcarcely to be diſcerned. Theſe worms are found the moſt predominant during the latter end of July and the beginning of Auguſt; at which time the plants muſt be particularly attended to, and every leaf carefully ſearched. As ſoon as a wound is diſcovered, and it will not be long before it is perceptible, care muſt be taken to deſtroy the cauſe of it, who will be found near it, and from his unſubſtantial texture may eaſily be cruſhed: but the beſt method is to pull it away by the horn, and then cruſh it.

When the tobacco is fit for being gathered, as will appear from an attention to the foregoing directions, on the firſt morning that promiſes a fair day, before the ſun is riſen, take an ax or a long knife, and holding the ſtalk near the top with one hand, ſever it from its root with the other, as low as poſſible. Lay it gently on the ground, taking care not to break off the leaves, and there let it remain expoſed to the rays of the ſun throughout the day, or until the leaves, according to the American expreſſion, are entirely *wilted;* that is, till they become limber; and will bend any way without breaking. But if the weather ſhould prove rainy without any intervals of ſunſhine, and the plants appear to be fully ripe, they muſt be houſed immediately. This muſt be done, however, with great care, that the leaves, which are in this ſtate very brittle, may not be broken. They are next to be placed under proper ſhelter, either in a barn or covered hovel, where they cannot be affected by rain or too much air, thinly ſcattered on the floor; and if the ſun does not appear for ſeveral days, they muſt by left to will in that manner; but in this caſe the quantity of the tobacco will not be quite ſo good.

When the leaves have acquired the above-mentioned flexibility, the plants muſt be laid in heaps, or rather in one heap if the quantity is not too great, and in about 24 hours they will be found to ſweat. But during this time, when they have lain for a little while, and begin to foment, it will be neceſſary to turn them; bringing thoſe which are in the middle to the ſurface, and placing thoſe which are at the ſurface in the middle. The longer they lie in this ſituation, the darker-coloured is the tobacco; and this is termed *ſweating* the tobacco. After they have lain in this manner for three or four days, for a longer continuance might make the plants turn mouldy, they may be faſtened together in pairs with chords or wooden pegs, near the bottom of the ſtalk, and hung acroſs a pole, with the leaves ſuſpended in the ſame covered place, a proper interval being left between each pair. In about a month the leaves will be thoroughly dried, and of a proper temperature to be taken down. This ſtate may be aſcertained by their appearing of the ſame colour with thoſe imported from America. But this can be done only in wet weather. —The tobacco is exceedingly apt to attract the humidity of the atmoſphere, which gives it a pliability that is abſolutely neceſſary for its preſervation; for if the plants are removed in a very dry ſeaſon, the external parts of the leaves will crumble into duſt, and a conſiderable waſte will enſue.

As ſoon as the plants are taken down, they muſt again be laid in a heap, and preſſed with heavy logs of wood for about a week; but this climate may poſſibly require a longer time. While they remain in this ſtate, it will be neceſſary to introduce your hand frequently into the heap, to diſcover whether the heat be not too intenſe; for in large quantities this will ſometimes be the caſe, and conſiderable damage will be occaſioned by it. When they are found to heat too much, that is, when the heat exceeds a moderate glowing warmth, part of the weight by which they are preſſed muſt be taken away; and the cauſe being removed, the effect will ceaſe. This is called the *ſecond* or *laſt ſweating;* and, when completed, which it generally will be about the time juſt mentioned, the leaves may be ſtripped from the ſtalks for uſe. Many omit this laſt ſweating; but Mr Carver thinks that it takes away any remaining harſhneſs, and renders the tobacco more mellow. The ſtrength of the ſtalk alſo is diffuſed by it through the leaves, and the whole maſs becomes equally meliorated.—When the leaves are ſtripped from the ſtalks, they are to be tied up in bunches or *hands*, and kept in a cellar or other damp place; though if not handled in dry weather,

weather, but only during a rainy ſeaſon, it is of little conſequence in what part of the houſe or barn they are laid up. At this period the tobacco is thoroughly cured, and as proper for manufacturing with that imported from the colonies.

Our author adviſes the tobacco-planter, in his firſt trials, not to be too avaricious, but to top his plants before they have gained their utmoſt height; leaving only about the middle quantity of leaves directed before, to give it a tolerable degree of ſtrength. For tho' this, if exceſſive, might be abated during the cure by an increaſe of ſweating, or be remedied the next ſeaſon by ſuffering more leaves to grow, it can never be added, and, without a certain degree of ſtrength, the tobacco will always be taſteleſs, and of little value. On the contrary, though it be ever ſo much weakened by ſweating, and thereby rendered mild, yet it will never loſe the aromatic flavour which accompanied that ſtrength, and which greatly adds to its value. A ſquare yard of land, he tells us, will rear about 500 plants, and allow proper ſpace for their nurture till they are fit for tranſplanting.

Tobacco has ſometimes been preſcribed internally; in which caſe it proves violently cathartic and emetic, occaſioning almoſt intolerable cardialgic anxieties. By boiling in water its virulence is abated, and at length deſtroyed. An extract made by long coction is recommended by Stahl and other German phyſicians, as a ſafe and moſt effectual aperient, expectorant, detergent, &c. but this medicine, which, according to Dr Lewis, is extremely precarious and uncertain in ſtrength, has never come into eſteem in this country. Tobacco is ſometimes uſed externally in unguents for deſtroying cutaneous inſects, cleanſing old ulcers, &c. Beaten into a maſh with vinegar or brandy, it has ſometimes proved ſerviceable for removing hard tumours of the hypochondres: an account is given in the Edinburgh Eſſays of two caſes of this kind cured by it. The moſt common uſes of this plant, however, are, either as a ſternutatory when taken by way of ſnuff, as a maſticatory by chewing it in the mouth, or as effluvia by ſmoking it; and when taken in moderation, it is not an unhealthy amuſement. Before pipes were invented, it was uſually ſmoked in ſegars, and they are ſtill in uſe among ſome of the ſouthern nations. The method of preparing theſe is at once ſimple and expeditious: A leaf of tobacco being formed into a ſmall twiſted roll, ſomewhat larger than the ſtem of a pipe, and about eight inches long, the ſmoke is conveyed through the winding folds which prevent it from expanding, as through a tube; ſo that one end of it being lighted, and the other applied to the mouth, it is in this form uſed without much inconvenience. But, in proceſs of time, pipes being invented, they were found more commodious vehicles for the ſmoke, and are now in general uſe.

Among all the productions of foreign climes introduced into theſe kingdoms, ſcarce any has been held in higher eſtimation by perſons of every rank than tobacco. In the countries of which it is a native, it is conſidered by the Indians as the moſt valuable offering that can be made to the beings they worſhip. They uſe it in all their civil and religious ceremonies. When once the ſpiral wreaths of its ſmoke aſcend from the feathered pipe of peace, the compact that has been juſt made is conſidered as ſacred and inviolable. Likewiſe, when they addreſs their great Father, or his guardian ſpirits, reſiding as they believe in every extraordinary production of nature, they make liberal offerings to them of this valuable plant, not doubting but that they are thus ſecured of protection.

Tobacco is made up into rolls by the inhabitants of the interior parts of America by means of a machine called a *tobacco-wheel*. With this machine they ſpin the leaves, after they are cured, into a twiſt of any ſize they think fit; and having folded it into rolls of about 20 pounds each, they lay it by for uſe. In this ſtate it will keep for ſeveral years, and be continually improving, as it always grows milder. The Illinois uſually form it into carrots; which is done by laying a number of leaves, when cured, on each other, after the ribs have been taken out, and rolling them round with pack-thread till they become cemented together. Theſe rolls commonly meaſure about 18 or 20 inches long, and nine round in the middle part.

Tobacco forms a very conſiderable article in commerce; for an account of which ſee the articles GLASGOW and VIRGINIA.

NICTITATING MEMBRANE, a thin membrane chiefly found in the bird and fiſh kind, which covers the eyes of theſe animals, ſheltering them from the duſt or too much light; yet is ſo thin and pellucid, that they can ſee pretty well through it.

NIDUS, among naturaliſts, ſignifies a neſt, or proper repoſitory for the eggs of birds, inſects, &c. where the young of theſe animals are hatched and nurſed.

NIDIFICATION, a term generally applied to the formation of a bird's neſt, and its hatching or bringing forth its young. See ORNITHOLOGY.

NIECE, a brother's or ſiſter's daughter, which in the civil law is reckoned the third degree of conſanguinity.

NIEMEN, a large river of Poland, which riſes in Lithuania, where it paſſes by Bielica, Grodno, and Konno: it afterwards runs thro' part of Samogitia and Ducal Pruſſia, where it falls into the lake called the *Curiſch-haff*, by ſeveral mouths, of which the moſt northern is called the *Ruſs*, being the name of a town it paſſes by.

NIENBURG, a rich and ſtrong town of Germany, in the duchy of Brunſwic-Lunenburg, with a ſtrong caſtle. It carries on a conſiderable trade in corn and wool, and is ſeated in a fertile ſoil on the river Weſer. E. Long. 9. 26. N. lat. 52. 44.

NIEPER, a large river of Europe, and one of the moſt conſiderable of the North, formerly called the Boriſthenes. Its ſource is in the middle of Muſcovy, running weſt by Smolenſko, as far as Orſa; and then turns ſouth, paſſing by Mohilow, Bohaczo, Kiow, Czyrkaſſy, the fortreſs of Kudak, Deſſau, and Oczakow, falling into the Black Sea; as alſo in its courſe it divides Little Tartary from Budziac Tartary.

NIESTER, a large river of Poland, which has its ſource in the Lake Neiſter, in the palatinate of Lemburg, where it paſſes by Halicz. Then it ſeparates Podolia and Oczakow Tartary from Moldavia and Budziac Tartary; and falls into the Black Sea at Belgorod, between the mouths of the Nieper and the Danube.

Nieuwentyt ‖ Night.

NIEUWENTYT (Bernard), an able philofopher and learned mathematician, was born at Weftgraafdyk, in the year 1654, and became counfellor and burgomafter of the town of Purmerend, where he was efteemed for his integrity and learning, and died in 1718. He wrote, in Dutch, 1. An excellent treatife, intitled, The Exiftence of God demonftrated by the works of nature. 2. A refutation of Spinoza. 3. Some pieces againft the Infiniteffimals, &c.

NIGELLA, FENNEL-FLOWER, or *Devil in a bufh*; a genus of the pentagynia order, belonging to the polyandria clafs of plants. There are five fpecies, all of them natives of the warm parts of Europe, and rifing from a foot to a foot and an half high, adorned with blue or yellow flowers. They are propagated by feeds, which in a dry and warm fituation will thrive very well; and the plants ripen feeds in this country.

NIGER, a great river of Africa, fuppofed to have its origin near that of the Nile; but this is very uncertain. We are affured, however, that it is a river of very great extent: efpecially if we fuppofe, according to the opinion of the beft modern geographers, that it has its fource in the kingdom of Gorhan, not far from the confines of Upper Ethiopia; for then it will crofs almoft the whole continent of Africa, where it is wideft. In its courfe it receives many confiderable rivers, which fwell it high enough to be able at all times to carry veffels of good burden; fo it fplits itfelf into feveral branches, which uniting again form very large and fertile iflands, well filled with towns and villages. It paffes alfo through feveral lakes, and has many cataracts. After having run from eaft to weft, during a prodigious long courfe, it turns at laft fhort to the fouth, at a leagne and a half diftance from the weftern ocean; leaving but a very narrow tract between it and the fea, into which it opens its way in lat. 15. 55. after having run about 25 leagues from north to fouth. Its mouth is fometimes half a league broad; but is fhut up by a bank of quick-fand called the *bar of Senegal*, where the water is fo fhallow, that it is very difficult and dangerous to pafs over it. The bar is formed by the mud and fand which the river brings with it during the inundation, and which the fea continually drives back upon the fhore. This would effectually exclude all fhipping, had not the violence of the current, and the weight of the waters, made two openings or channels, which are commonly called the *paffes of the bar*. The largeft of thefe is generally not above 150 or 200 fathoms broad, and about 10 feet deep, fo that none but barks of 40 or 50 tons can get through this channel; the other is fo narrow and fhallow, that it is paffable by canoes only. Thefe channels are not always in the fame place; for the river, as it is more or lefs fwelled, or the current more or lefs rapid, opens thofe paffes fometimes in one place, and fometimes in another. The bar itfelf alfo frequently fhifts its place; fo that the ifland of Senegal is fometimes four leagues diftant from it, at other times only two. It is this bar only which hinders fhips of 400 or 500 tons to go up the river.

NIGHT, that part of the natural day during which the fun is underneath the horizon; or that fpace wherein it is dufky.

Night was originally divided by the Hebrews and other eaftern nations into three parts or watches. The Romans, and after them the Jews, divided the night into four parts or watches; the firft of which began at funfet, and lafted till nine at night, according to our way of reckoning; the fecond lafted till midnight; the third till three in the morning; and the fourth ended at funrife. The ancient Gauls and Germans divided their time not by days but nights; and the people of Iceland and the Arabs do the fame at this day. The like is obferved of the Anglo-Saxons.

Night, Nightingale.

NIGHT-*Angling*, a method of catching large and fhy fifh in the night-time. Trout, and many other of the better forts of fifh, are naturally fhy and fearful; they therefore prey in the night as the fecureft time.—The method of taking them on this plan is as follows. The tackle muft be ftrong, and need not be fo fine as for day-fifhing, when every thing is feen; the hook muft be baited with a large earth-worm, or a black fnail, and thrown out into the river; there muft be no lead to the line, fo that the bait may not fink, but be kept drawling along, upon or near the furface. Whatever trout is near the place will be brought thither by the motion of the water, and will feize the worm or fnail. The angler will be alarmed by the noife which the fifh makes in rifing, and is to give him line, and time to fwallow the hook; then a flight touch fecures him. The beft and largeft trouts are found to bite thus in the night; and they rife moftly in the ftill and clear deeps, not in the fwift and fhallow currents. Sometimes, though there are fifh about the place, they will not rife at the bait; in this cafe the angler muft put on fome lead to his line, and fink it to the bottom.

NIGHT-*Mare*, or *Incubus*. See MEDICINE, n° 430.

NIGHT-*Walkers*, in medicine. See NOCTAMBULI.

NIGHT-*Walkers*, in law, are fuch perfons as fleep by day and walk by night, being oftentimes pilferers or difturbers of the public peace. Conftables are authorifed by the common law to arreft night-walkers and fufpicious perfons, &c. Watchmen may alfo arreft night-walkers, and hold them until the morning: and it is faid, that a private perfon may arreft any fufpicious night-walker, and detain him till he give a good account of himfelf. One may be bound to the good behaviour for being a night-walker; and common night-walkers, or haunters of bawdy-houfes, are to be indicted before juftices of peace, &c. But it is not held lawful for a conftable, &c. to take up any woman as a night-walker on bare fufpicion only of being of ill fame, unlefs fhe be guilty of a breach of the peace, or fome unlawful act, and ought to be found mifdoing. *Blackft. Comment.*

NIGHTINGALE, in ornithology; a fpecies of MOTACILLA; under which article it happened to be omitted.

The nightingale takes its name from *night*, and the Saxon word *galan*, " to fing;" expreffive of the time of its melody. In fize it is equal to the redftart; but longer-bodied, and more elegantly made. The colours are very plain. The head and back are of a pale tawny, dafhed with olive: the tail is of a deep tawny red: the throat, breaft, and upper part of the belly, of a light gloffy afh-colour: the lower belly almoft white: the exterior webs of the quill-feathers are of a dull reddifh brown; the interior of brownifh afh-colour: the irides are hazel, and the eyes remarkably large

large and piercing: the legs and feet a deep ash-colour.

This bird, the most famed of the feathered tribe, for the variety, length, and sweetness of its notes, visits England the beginning of April, and leaves us in August. It is a species that does not spread itself over the island. It is not found in North Wales; or in any of the English counties north of it, except Yorkshire, where they are met with in great plenty about Doncaster. They have been also heard, but rarely, near Shrewsbury. It is also remarkable, that this bird does not migrate so far west as Devonshire and Cornwall; counties where the seasons are so very mild, that myrtles flourish in the open air during the whole year: neither are they found in Ireland. Sibbald places them in his list of Scotch birds; but they certainly are unknown in that part of Great Britain, probably from the scarcity and the recent introduction of hedges there. Yet they visit Sweden, a much more severe climate. In England they frequent thick hedges, and low coppices; and generally keep in the middle of the bush, so that they are very rarely seen. They form their nest of oak leaves, a few bents and reeds. The eggs are of a deep brown. When the young ones first come abroad, and are helpless, the old birds make a plaintive and jarring noise with a sort of snapping as if in menace, pursuing along the hedge the passengers.

They begin their song in the evening, and continue it the whole night These their vigils did not pass unnoticed by the ancients: the slumbers of these birds were proverbial; and not to rest as much as the nightingale, expressed a very bad sleeper (A). This was the favourite bird of the British poet, who omits no opportunity of introducing it, and almost constantly noting its love of solitude and night. How finely does it serve to compose part of the solemn scenery of his *Penseroso;* when he describes it

In her saddest sweetest plight,
Smoothing the rugged brow of night;
While *Cynthia* checks her dragon yoke,
Gently o'er th' accustom'd oak.
Sweet bird, that shunn'st the noise of folly,
Most musical, most melancholy!
Thee, chauntress, oft the woods among,
I woo to hear thy evening song.

In another place he styles it the *solemn bird;* and again speaks of it,

As the wakeful bird
Sings darkling, and, in shadiest covert hid,
Tunes her nocturnal note.

The reader will excuse a few more quotations from the same poet, on the same subject; the first describes the approach of evening, and the retiring of all animals to their repose.

Silence accompanied; for beast and bird,
They to their grassy couch, these to their nests
Were slunk; all but the wakeful *nightingale*,
She all night long her amorous descant sung.

When Eve passed the irksome night preceding her fall, she, in a dream, imagines herself thus reproached with losing the beauties of the night by indulging too long a repose.

Why sleep'st thou, *Eve?* now is the pleasant time,
The cool, the silent, save where silence yields
To the night-warbling bird, that now awake
Tunes sweetest his love-labour'd song.

The same birds sing their nuptial song, and lull them to rest. How rapturous are the following lines! how expressive of the delicate sensibility of our Milton's tender ideas!

The earth
Gave sign of gratulation, and each hill;
Joyous the birds; fresh gales and gentle airs
Whisper'd it to the woods, and from their wings
Flung rose, flung odours from the spicy shrub,
Disporting, till the amorous bird of night
Sung sponsal, and bid haste the evening star
On his hill-top to light the bridal lamp.
These, lull'd by *nightingales*, embracing slept;
And on their naked limbs the flowery roof
Shower'd roses, which the morn repair'd.

These quotations from the best judge of melody, we thought due to the sweetest of our feathered choiristers; and we believe no reader of taste will think them tedious.

Virgil seems to be the only poet among the ancients who hath attended to the circumstance of this bird's singing in the night time.

Qualis populeâ mœrens Philomela *sub umbrâ*
Amissos queritur fœtus, quos durus arator
Observans nido implumes detraxit: at illa
Flet noctem, ramoque sedens miserabile carmen
Integrat, et mœstis late loco questibus implet.
Georg. IV. l. 511.

As *Philomel* in poplar shades, alone,
For her lost offspring pours a mother's moan,
Which some rough ploughman marking for his prey,
From the warm nest, unfledg'd hath dragg'd away;
Percht on a bough, she all night long complains,
And fills the grove with sad repeated strains. *F. Warton.*

Pliny has described the warbling notes of this bird, with an elegance that bespeaks an exquisite sensibility of taste, *lib.* x. *c.* 29.

If the nightingale is kept in a cage, it often begins to sing about the latter end of November, and continues its song more or less till June.—A young canary-bird, linnet, sky-lark, or robin (who have never heard any other bird), are said best to learn the note of a nightingale.

NIGHTSHADE, in botany. See SOLANUM.

Deadly NIGHTSHADE. See ATROPA. The berries of this plant are of a malignant poisonous nature; and, being of a sweet taste, have frequently proved destructive to children. A large glass of warm vinegar, taken as soon as possible after eating the berries, will prevent their bad effects.

NIGIDIUS FIGULUS (Publius), one of the most learned men of ancient Rome, flourished at the same time with Cicero. He wrote on various subjects; but his pieces appeared so refined and difficult, that they were not regarded. He assisted Cicero, with great prudence, in defeating Catiline's conspiracy, and did him many services in the time of his adversity. He adhered to Pompey, in opposition to Cæsar; which occasioned his exile, he dying in banishment. Cicero, who had always entertained the highest esteem for him, wrote a beautiful consolatory letter to him, (the 13th of *lib.* 4. *ad Familiares.*)

NIGRITIA. See NEGROLAND.

NILE, a great river of Egypt in Africa, which has

(A) *Ælian var. hist.* 577. both in the text and note. It must be remarked, that nightingales sing also in the day.

has its fource in Abyffinia, in about eight degrees north latitude. It runs generally from fouth to north through Abyffinia, Senna, and Nubia, into Egypt in one ftream, till it comes below Cairo to the Delta, where it divides into feveral branches, the two principal of which difcharge themfelves into the Mediterranean, the one at Damietta, and the other at Rofetta. There are feveral cataracts in this river in Upper Egypt, but not fo dreadful as ancient authors have reported. There are great rejoicings every year in Egypt when the Nile rifes to a certain height, becaufe their future harveft depends upon it. At the time of its rifing they publifh every day how many cubits and inches it is rifen. But to know this, we muft remember, that each cubit contains 24 inches: when the water is augmented to 16 cubits, then they open a fluice, which runs crofs the city of Cairo; and when it is come to 22 cubits, it is reckoned very advantageous, if it afcends no higher: but if it rifes to 24, it puts them into a terrible confternation, and then they publifh that it extends from one mountain to the other. They are likewife in a great fright when the water afcends very flowly, becaufe they are then afraid that it will not rife high enough to render the land fertile. The inundation generally continues from the 20th of July to the beginning of November; at which time the dry land begins to appear, if it can be called dry, after it has been fo long foaked in the water. As foon as the land is fit, they fow their corn, and in April it becomes yellow and fit for reaping. When the water is let into the great canal, it is conveyed from thence into refervoirs and cifterns, to be diftributed into their fields and gardens. But all the low wet places are fowed with rice, which grows beft in the water. This overflowing of the Nile is owing to the great rains which fall annually between the tropics upon the high mountains of Abyffinia, near which the fource of the Nile is, and from which the water falls down in great torrents into that river. The Nile does not contain a great number of fifh, perhaps becaufe there are fo many crocodiles and other voracious animals. The water, when it is clear, is very fit for drinking.

NIMBUS, in antiquity, a circle obferved on certain medals, or round the heads of fome emperors; anfwering to the circles of light drawn round the images of faints.

NIMEGUEN, a large, handfome, and ftrong town of the Netherlands, and capital of Dutch Guelderland, with a citadel, an ancient palace, and feveral forts. It is noted for the peace concluded there in 1679. It has a magnificent town-houfe, and the inhabitants are greatly addicted to trade. It is feated on the Vahal or Wahal, between the Rhine and the Maefe, in Long. 5. 50. Lat. 51. 55.

NIMETULAHITES, a kind of Turkifh monks, fo called from their founder Nimetulahi, famous for his doctrines and the aufterity of his life.

NIMPO, a city and fea-port town of China, in the province of Chekiang. It is feated on the eaftern fea of China, over-againft Japan. It is a city of the firft rank, and ftands at the confluence of two fmall rivers, which, after their union, form a channel that reaches to the fea, and is deep enough to bear veffels of 200 tons burthen. The walls of Nimpo are 5000 paces in circumference, and are built with free-ftone. There are five gates, befides two water-gates for the paffage of barks into the city; a tower feveral ftories high, built of bricks; and a long bridge of boats, faftened together with iron chains, over a very broad canal. This city is commanded by a citadel built on a very high rock, by the foot of which all veffels muft neceffarily pafs. The Chinefe merchants of Siam and Batavia go to this place yearly to buy filks, which are the fineft in the empire. They have alfo a great trade with Japan, it being but two days fail from hence: thither they carry filks, ftuffs, fugar, drugs, and wine; and bring back copper, gold, and filver. E. Long. 122. 0. N. Lat. 30. 0.

NINEVEH (anc. geogr.), a city of Affyria, which is thought to be one of the moft ancient in the world. It was enlarged by Ninus, who fome take to be the *Nimrod* of Mofes. When Jonas went to preach againft it, he was faid to be three days in paffing through it. It was a long while the capital of the Affyrian empire; but is now ruined, and it is hard to find the place where it ftood.

NINON LENCLOS, a celebrated lady in the court of France, was of a noble family, and born at Paris in the year 1615; but rendered herfelf famous by her wit and gallantries. Her mother was a lady of exemplary piety; but her father early infpired her with the love of pleafure. Having loft her parents at 14 years of age, and finding herfelf miftrefs of her own actions, fhe refolved never to marry: fhe had an income of 10,000 livres a-year; and, according to the leffons fhe had received from her father, drew up a plan of life and gallantry, which fhe purfued till her death. Never delicate with refpect to the number, but always in the choice, of her pleafures, fhe facrificed nothing to intereft; but loved only while her tafte for it continued; and had among her admirers the greateft lords of the court. But though fhe was light in her amours, fhe had many virtues.—She was conftant in her friendfhips; faithful to what are called the *laws of honour;* of ftrict veracity; difinterefted; and more particularly remarkable for the exacteft probity. Women of the moft refpectable characters were proud of the honour of having her for their friend: at her houfe was an affemblage of every thing moft agreeable in the city and the court; and mothers were extremely defirous of fending their fons to that fchool of politenefs and good tafte, that they might learn fentiments of honour and probity, and thofe other virtues that render men amiable in fociety. But the illuftrious Madame de Sevigné with great juftice remarks in her letters, that this fchool was dangerous to religion and the Chriftian virtues; becaufe Ninon Lenclos made ufe of feducing maxims, capable of depriving the mind of thofe invaluable treafures. Ninon was efteemed beautiful, even in old age; and is faid to have infpired violent paffions at 80. She died at Paris in 1705. This lady had feveral children; one of whom, named *Chevalier de Villiers,* occafioned much difcourfe by the tragical manner in which he ended his life. He became in love with Ninon, without knowing that fhe was his mother; and when he difcovered the fecret of his birth, ftabbed himfelf in a fit of defpair. There have been publifhed the pretended Letters of Ninon Lenclos to the marquis de Sevigné.

NINTH, in mufic. See INTERVAL.

NINUS, the firft king of the Affyrians, was, it is faid, the fon of Belus. It is added, that he enlarged Nineveh and Babylon; conquered Zoroafter king of the Bactrians; married Semiramis of Afcalon; fubdued almoft all Afia; and died after a glorious reign of 52 years, about 1150 B. C.; but all thefe facts are uncertain. See SEMIRAMIS.

NIO, an ifland of the Archipelago, between Naxi to the north, Armago to the eaft, Santerino to the fouth, and Sikino to the weft, and is about 35 miles in circumference. It is remarkable for nothing but Homer's tomb, which they pretend is in this ifland; for they affirm that he died here in his paffage from Samos to Athens. The ifland is well cultivated, and not fo fteep as the other iflands, and the wheat which it produces is excellent; but oil and wood are fcarce. It is fubject to the Turks. E. Long. 25. 53. N. Lat. 36. 35.

NIOBE, in fabulous hiftory, the daughter of Tantalus, and the wife of Amphion king of Thebes, was a princefs of great beauty; but being the mother of feven fons and as many daughters, fhe had the prefumption to prefer herfelf to Latona, who had only Apollo and Diana. Latona enraged at this contempt, caufed Apollo and Diana to kill Niobe's 14 children with their arrows, the former flaying the fons, and the latter the daughters, in the embraces of their mother. On which Niobe being filled with the deepeft grief, Jupiter, in compaffion to her inceffant tears, turned her into ftone.

NIPHON, the largeft of the Japan iflands, being 600 miles long, and 100 broad. See JAPAN.

NIPPERS, in the menage, are four teeth in the fore-part of a horfe's mouth, two in the upper, and two in the lower jaw. A horfe puts them forth between the fecond and third year.

NIPPLES, in anatomy. See there, n° 376, c.

NIPPLE-WORT, in botany. See LAPSANA.

NISI PRIUS, in law, a judicial writ which lies in cafes where the jury being impanelled and returned before the juftices of the bank, one of the parties requefts to have fuch a writ for the eafe of the country, in order that the trial may come before the juftices in the fame county on their coming thither. The purport of a writ of *nifi prius* is, that the fheriff is thereby commanded to bring to Weftminfter the men impanelled, at a certain day, before the juftices, "*nifi prius jufticiarii domini regis ad affifas capiendas venerint.*"

NISIBIS (anc. geog.), a city both very ancient and noble, fituate in a diftrict called *Mygdonia*, in the north of Mefopotamia, towards the Tigris, from which it is diftant two days journey. Some afcribe its origin to Nimrod, and fuppofe it to be the *Achad* of Mofes. The Macedonians called it *Antiochia of Mygdonia*, (Plutarch); fituate at the foot of mount Mafius, (Strabo). It was the Roman bulwark againft the Parthians and Perfians, down to the emperor Jovianus; who, by an ignominious peace, delivered it up to the Perfians. A colony, called *Septimia Nefibitana.*— Another *Nifibis*, of Aria, (Ptolemy), near the lake Arias.

NISMES, an ancient, large, and flourifhing town of France, in Languedoc, with a bifhop's fee, and an academy. There are feveral monuments of antiquity, of which the amphitheatre is the principal, built by the Romans. The *maifon quarrée*, or the fquare-houfe, is a piece of architecture of the Corinthian order, and one of the fineft in the world. The temple of Diana is in part gone to ruin. It was taken by the Englifh in 1417. The inhabitants were all Calvinifts; but Lewis XIV. demolifhed their church in 1685, and built a caftle to keep them in awe. It is feated in a delightful plain, abounding in wine, oil, game, and cattle. E. Long. 4. 26. N. Lat. 43. 50.

NITHSDALE, NITHISDALE, or *Niddifdale*, a divifion of Dumfriesfhire in Scotland, lying to the weftward of Anandale. It is a large and mountainous tract, deriving its name from the river Nid, which iffues from a lake called *Loch-cure*, runs by the towns of Sanquhar, Morton, and Drumlanrig, and difcharges itfelf into the Solway Frith. This country was formerly fhaded with noble forefts, which are now almoft deftroyed; fo that, at prefent, nothing can be more naked, wild, and favage. Yet the bowels of the earth yields lead, and, as is faid, filver and gold: the mountains are covered with fheep and black cattle; and here are ftill fome confiderable remains of the ancient woods, particularly that of Holywood, three miles from Dumfries, noted for an handfome church built out of the ruins of an ancient abbey; and alfo for being the birth-place of the famous aftrologer, hence called *Joannes de Sacro Bofco.*

NITRE, or SALTPETRE. See CHEMISTRY, n° 184.

Calcareous NITRE. Ibid. n° 191.

Cubic NITRE. Ibid. n° 185.

NITROUS, any thing impregnated with nitre.

NITROUS *Air*. See AIR, n° 36, 39.; EUDIOMETER, note (B); and AIR, in the APPENDIX.

NIVELLE, a town of the Auftrian Netherlands, in the province of Brabant, remarkable for its abbey of Canoneffes. Here is a manufacture of cambrics, and the town enjoys great privileges. The abbey juft mentioned is inhabited by young ladies of the firft quality, who are not confined therein as in nunneries, but may go out and marry whenever they fee convenient, or a proper match offers. E. Long. 4. 20. N. Lat. 50. 46.

NIVELLE *de la Chauffée* (Peter Claude), a comic poet, born at Paris; acquired great reputation by inventing a new kind of entertainment, which was called *the Weeping Comedy.* Inftead of imitating Ariftophanes, Terence, Moliere, and the other celebrated comic poets who had preceded him; and inftead of exciting laughter by painting the different ridiculous characters, giving ftrokes of humour and abfurdities in conduct; he applied himfelf to reprefent the weakneffes of the heart, and to touch and foften it. In this manner he wrote five comedies: 1. *La fauffe Antipathie.* 2. *Le Préjugé à la Mode;* this piece met with great fuccefs. 3. *Mélanide.* 4. *Amour pour Amour;* and, 5. *L'Ecole des Meres.* He was received into the French academy in 1736; and died at Paris in 1754, at 63 years of age. He alfo wrote a tragedy, intitled, *Maximianus;* and an epiftle to Clio, an ingenious didactic poem.

NIVERNOIS, a province of France, with the title of a *duchy*, between Burgundy, Bourbonnois, and Barri. It is pretty fertile in wine, fruit, and corn; except the part

part called *Morvant*, which is a mountainous country, and barren. There is agreat deal of wood, and feveral iron mines; as alfo mines of pit-coal, which ferves to work their forges. This province is watered by a great number of rivers; of which the Allier, the Loire, and the Yonne, are navigable. Nevers is the capital city.

NIXAPA, a rich and confiderable town in New Spain, with a rich convent of Dominicans. The country about it abounds in cochineal, indigo, and fugar. E. Long. 97. 25. N. Lat. 15. 20.

NO, (Jeremiah, Ezekiel), No-Ammon, (Nahum); a confiderable city of Egypt, thought to be the name of an idol which agrees with Jupiter-Ammon. The Septuagint tranflate the name in Ezekiel, *Diofpolis*, "the city of Jupiter." Bochart takes it to be *Thebes* of Egypt; which, according to Strabo and Ptolemy, was called *Diofpolis*. Jerome, after the Chaldee paraphraft Jonathan, fuppofes it to be Alexandria, named by way of anticipation; or an ancient city of that name is fuppofed to have ftood on the fpot where Alexandria was built.

No-*Man's-Land*, a fpace between the after-part of the belfrey and the fore-part of a fhip's boat, when the faid boat is ftowed upon the booms, as in a deep-waifted veffel. Thefe booms are laid from the forecaftle nearly to the quarter-deck, where their after-ends are ufually fuftained by a frame called the *gallows*, which confifts of two ftrong pofts, about fix feet high, with a crofs piece reaching from one to the other, athwart-fhips, and ferving to fupport the ends of thofe booms, mafts, and yards, which lie in referve to fupply the place of others carried away, &c. The fpace called *No-man's-land* is ufed to contain any blocks, ropes, tackles, &c. which may be neceffary on the forecaftle. It probably derives this name from its fituation, as being neither on the ftarboard nor larboard fide of the fhip, nor on the waift or forecaftle; but, being fituated in the middle, partakes equally of all thofe places.

NOAH, a famous patriarch, was the fon of Lamech, and was born in 2978 B.C. He alone with his family were preferved from the univerfal deluge, when God exterminated the reft of the human race on account of their crimes. Having by the divine command built an ark, he entered it with his wife, his three fons and their wives, and animals of every kind, who were to multiply upon the earth after the deluge. Noah and all the living creatures ftaid a year in that veffel; and, on his coming out, he immediately expreffed his gratitude by erecting an altar to the Lord, and offering facrifices.—On which God bleffed Noah and his family, and promifed that the waters fhould no more overflow the whole earth. He died at the age of 950, 350 years after the deluge; leaving three fons, Shem, Ham, and Japheth, from whom fprung the whole human race.

NOBILIARY, in literary hiftory, a book containing the hiftory of the noble families of a nation, or province: fuch are Choriere's Nobiliary of Dauphine, and Caumartin's Nobiliary of Provence. The Germans are faid to be particularly careful of their Nobiliaries, in order to keep up the dignity of their families.

NOBILITY, a quality that ennobles, and raifes a perfon poffeffed of it above the rank of a commoner.

The origin of nobility in Europe is by fome referred to the Goths; who, after they had feized a part of Europe, rewarded their captains with titles of honour, to diftinguifh them from the common people.—In this place we fhall confider the manner in which they may be created, and the incidents attending them.

1. The right of peerage feems to have been originally territorial; that is, annexed to lands, honours, caftles, manors, and the like, the proprietors and poffeffors of which were (in right of thofe eftates) allowed to be peers of the realm, and were fummoned to parliament to do fuit and fervice to their fovereign: and, when the land was alienated, the dignity paffed with it as appendant. Thus the bifhops ftill fit in the houfe of lords in right of fucceffion to certain ancient baronies annexed, or fuppofed to be annexed, to their epifcopal lands; and thus, in 11 Hen. VI. the poffeffion of the caftle of Arundel was adjudged to confer an earldom on its poffeffor. But afterwards, when Alienations grew to be frequent, the dignity of peerage was confined to the lineage of the party ennobled, and inftead of territorial became perfonal. Actual proof of a tenure by barony became no longer neceffary to conftitute a lord of parliament; but the record of the writ of fummons to him or his anceftors was admitted as a fufficient evidence of the tenure.

Peers are now created either by writ or by patent: for thofe who claim by prefcription muft fuppofe either a writ or patent made to their anceftors; tho' by length of time it is loft. The creation by writ, or the king's letter, is a fummons to attend the houfe of peers, by the ftyle and title of that barony which the king is pleafed to confer: that by patent is a royal grant to a fubject of any dignity and degree of peerage. The creation by writ is the more ancient way; but a man is not ennobled thereby, unlefs he actually take his feat in the houfe of lords: and fome are of opinion that there muft be at leaft two writs of fummons, and a fitting in two diftinct parliaments, to evidence an hereditary barony: and therefore the moft ufual, becaufe the fureft, way is to grant the dignity by patent, which endures to a man and his heirs according to the limitations thereof, though he never himfelf makes ufe of it. Yet it is frequent to call up the eldeft fon of a peer to the houfe of lords by writ of fummons, in the name of his father's barony: becaufe in that cafe there is no danger of his children's lofing the nobility in cafe he never takes his feat; for they will fucceed to their grandfather. Creation by writ has alfo one advantage over that by patent: for a perfon created by writ holds the dignity to him and his heirs, without any words to that purport in the writ; but in latters patent there muft be words to direct the inheritance, elfe the dignity endures only to the grantee for life. For a man or woman may be created noble for their own lives, and the dignity not defcend to their heirs at all, or defcend only to fome particular heirs: as where a peerage is limited to a man and the heirs male of his body by Elizabeth his prefent lady, and not to fuch heirs by any former or future wife.

Blackft. Comment.

2. Let us next take a view of a few of the principal incidents attending the nobility,—exclufive of their capacity

Nobility. capacity as members of parliament, and as hereditary counsellors of the crown, both of which we have considered under the articles LORDS and PARLIAMENT. And first we must observe, that in criminal cases a nobleman shall be tried by his peers. The great are always obnoxious to popular envy: were they to be judged by the people, they might be in danger from the prejudice of their judges; and would moreover be deprived of the privilege of the meanest subjects, that of being tried by their equals, which is secured to all the realm by magna carta, c. 29. It is said, that this does not extend to bishops; who, though they are lords of parliament, and sit there by virtue of their baronies which they hold *jure ecclesiæ*, yet are not ennobled in blood, and consequently not peers with the nobility. As to peeresses, no provision was made for their trial when accused of treason or felony, till after Eleanor duchess of Gloucester, wife to the lord protector, had been accused of treason, and found guilty of witchcraft, in an ecclesiastial synod, through the intrigues of cardinal Beaufort. This very extraordinary trial gave occasion to a special statute, 20 Hen. VI. c. 9. which enacts, that peeresses, either in their own right or by marriage, shall be tried before the same judicature as peers of the realm. If a woman, noble in her own right, marries a commoner, she still remains noble, and shall be tried by her peers: but if she be only noble by marriage, then by a second marriage with a commoner she loses her dignity; for by marriage it is gained, by marriage it is also lost. Yet if a duchess-dowager marries a baron, she continues a duchess still; for all the nobility are *pares*, and therefore it is no degradation. A peer or peeress (either in her own right or by marriage) cannot be arrested in civil cases: and they have also many peculiar privileges annexed to their peerage in the course of judicial proceedings. A peer sitting in judgment, gives not his verdict upon oath, like an ordinary juryman, but upon his honour; he answers also to bills in chancery upon his honour, and not upon his oath; but, when he is examined as a witness either in civil or criminal cases, he must be sworn; for the respect which the law shews to the honour of a peer does not extend so far as to overturn a settled maxim, that *in judicio non creditur nisi juratis*. The honour of peers is however so highly tendered by the law, that it is much more penal to spread false reports of them, and certain other great officers of the realm, than of other men: scandal against them being called by the peculiar name of *scandalum magnatum*, and subjected to peculiar punishment by divers ancient statutes.

A peer cannot lose his nobility but by death or attainder; though there was an instance, in the reign of Edward the fourth, of the degradation of George Nevile duke of Bedford by act of parliament, on account of his poverty, which rendered him unable to support his dignity. But this is a singular instance: which serves at the same time, by having happened, to shew the power of parliament; and, by having happened but once, to shew how tender the parliament hath been, in exerting so high a power. It hath been said indeed, that if a baron wastes his estate, so that he is not able to support the degree, the king may degrade him: but it is expresly held by later authorities, that a peer cannot be degraded but by act of parliament.

Noble ‖ Nocturnal.

NOBLE, a money of account containing six shillings and eight pence.

The noble was anciently a real coin struck in the reign of Edward III. and then called the *penny of gold;* but it was afterwards called a *rose-noble*, from its being stamped with a rose: it was current at 6s. 8d.

NOCERA, an ancient town of Italy, in the duchy of Spoletto, and in the territory of the pope, with a bishop's see; seated at the foot of the Appennines, E. Long. 12. 55. N. Lat. 43. 2.

Terra NOCERIANA, *Earth of Nocera*, in the materia medica, a species of bole remarkably heavy, of a greyish-white colour, of an insipid taste, and generally with some particles in it which grit between the teeth. It is much esteemed by the Italians, as a remedy for venomous bites, and in fevers; but, excepting as an absorbent and astringent, no dependence is to be had on it.

NOCTAMBULI, NOCTAMBULONES, or *Night-walkers;* a term of equal import with *somnambuli*, applied to persons who have a habit of rising and walking about in their sleep. The word is a compound of the Latin *nox*, "night," and *ambulo*, "I walk."

Schenckius, Horstius, Clauderus, and Hildanus, who have wrote of sleep, give us divers unhappy histories of such noctambuli. When the disease is moderate, the persons affected with it only repeat the actions of the day on getting out of bed, and go quietly to the places they frequented at other times; but those who have it in the most violent degree, go up to dangerous places, and do things which would terrify them to think of when they are awake. These are by some caled *lunatic* night-walkers, because fits are observed to return with the most frequency and violence at the changes of the moon.—For the cure some recommend purging and a cooling regimen: others are of opinion that the best method is to place a vessel of water at the patient's bed-side in such a manner that he will naturally step into it when he gets out of bed; or if that should fail, a person should sit up to watch and beat him every time it happens.

NOCTILUCA, a species of phosphorus, so called because it shines in the dark without any light being thrown upon it: such is the phosphorus made of urine.

NOCTURNAL, something relating to the night, in contradiction to diurnal.

NOCTURNAL, *Nocturlabium*, an instrument chiefly used at sea, to take the altitude or depression of some stars about the pole, in order to find the latitude and hour of the night.

Some nocturnals are hemispheres, or planispheres, on the plane of the equinoctial. Those commonly in use among seamen are two; the one adapted to the polar star, and the first of the guards of the little bear; the other to the pole star, and the pointers of the great bear.

This instrument consists of two circular plates, applied to each other. The greater, which has a handle to hold the instrument, is about $2\frac{1}{2}$ inches diameter, and is divided into twelve parts, agreeing to the twelve months; and each month subdivided into every fifth

fifth day; and so as that the middle of the handle corresponds to that day of the year wherein the star here regarded has the same right ascension with the sun. If the instrument be fitted for two stars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts for the twenty-four hours of the day, and each hour subdivided into quarters. These twenty-four hours are noted by twenty-four teeth to be told in the night. Those at the hours 12, are distinguished by their length. In the centre of the two circular plates is adjusted a long index, moveable upon the upper plate. And the three pieces, viz. the two circles and index, are joined by a rivet which is pierced through the centre with a hole, through which the star is to be observed.

Plate CCI. fig. 2.

To use the nocturnal, turn the upper plate till the long tooth, marked 12, be against the day of the month on the under plate: then, bringing the instrument near the eye, suspend it by the handle with the plane nearly parallel to the equinoctial; and viewing the pole star through the hole of the centre, turn the index about, till, by the edge coming from the centre, you see the bright star or guard of the little bear, (if the instrument be fitted to that star): then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour-circle: which may be known without a light, by counting the teeth from the longest, which is for the hour 12.

NODATED HYPERBOLA, a name given by Sir Isaac Newton to a kind of hyperbola, which, by turning round, decussates or crosses itself.

NODE, a tumour arising on the bones, and usually proceeding from some venereal cause; being much the same with what is otherwise called *exostosis*.

NODES, in astronomy, the two points where the orbit of a planet intersects the ecliptic.

Plate CCIV. fig. 4. n° 1.

Such are the two points C and D; of which the node C, where the planet ascends northward above the plane of the ecliptic, is called the *ascending node*, or the *dragon's head*, and is marked thus ☊. The other node D, where the planet descends to the south, is called the *descending node*, or the *dragon's tail*, marked thus ☋.

The line CD, wherein the two circles C E D F and C G D H intersect, is called the *line of nodes*. It apprears from observation, that the line of the nodes of all the planets, constantly changes its place, and shifts its situation from east to west, contrary to the order of the signs; and that the line of the moon's nodes, by a retrograde motion, finishes it circulation in the compass of 19 years; after which time, either of the nodes having receded from any point of the ecliptic, returns to the same again; and when the moon is in the node, she is also seen in the ecliptic. If the line of nodes were immoveable, that is, if it had no other motion than that whereby it is carried round the sun, it would always look to the same point of the ecliptic, or would keep parallel to itself, as the axis of the earth does.

From what hath been said, it is evident, that the moon can never be observed precisely in the ecliptic, but twice in every period; that is, when she enters the nodes. When she is at her greatest distance from the nodes; viz. in the points E, F, she is said to be in her limits.

The moon must be in or near one of the nodes, when there is an eclipse of the sun or moon.

To make the foregoing account of the motion of moon's nodes still clearer, let the plane of n° 2. *ibid.* represent that of the ecliptic, S the sun, T the centre of the earth, L the moon in her orbit D N *d n*. N *n* is the line of the nodes passing between the quadrature Q, and the moon's place L, in her last quarter. Let now L P, or any part L S, represent the excess of the sun's action at T; and this being resolved into the force L R, perpendicular to the plane of the moon's orbit, and P R parallel to it, it is the former only that has any effect to alter the position of the orbit, and in this it is wholly exerted. Its effect is twofold: 1. It diminishes its inclination by a motion which we may conceive as performed round the diameter D *d*, to which L T is perpendicular. 2. Being compounded with the moon's tangential motion at L, it gives it an intermediate direction L *t*, through which, and the centre, a plane being drawn, must meet the ecliptic nearer the conjunction C than before.

NODUS, or node, in dialling, a certain point or pole in the gnomon of a dial, by the shadow or light whereof either the hour of the day in dials without furniture, or the parallels of the sun's declination, and his place in the ecliptic, &c. in dials with furniture, are shewn. See DIALLING.

NOEOMAGUS LEXUVIORUM, (Ptol.); thought to be the *Civitas Lexoviorum* of the lower age. Now *Lisieux*, a city in Normandy.—Another of the *Tricastini*; a town of Gallia Narbonensis; thought to be *S. Pol de Trois Châteaux*, six miles to the west of Nyons in Dauphiné.

NOETIANS, in church-history, Christian heretics in the third century, followers of Noetius, a philosopher of Ephesus, who pretended that he was another Moses sent by God, and that his brother was a new Aaron. His heresy consisted in affirming that there was but one person in the Godhead; and that the Word and the Holy Spirit were but external denominations given to God in consequence of different operations: that as Creator, he is called *Father*; as Incarnate, *Son*; and as descending on the apostles, *Holy Ghost*.

NOLA, a very ancient city, formerly populous and strong, situate in a plain to the north-east of Vesuvius in Campania, said to be built by the Chalcidians, (Justin, Silius Italicus); according to others, by the Tuscans. At this place Hannibal met with the first check by Marcellus. Vespasian added the appellation *Augusta Colonia*, (Frontinus). At this place, or in its neighbourhood, Augustus is said to have expired. At this day retaining its old name, but fallen short of its ancient splendour. A town of the kingdom of Naples. E. Long. 15. N. Lat. 41. 5.

NOLLE PROSEQUI, is where a plaintiff in an action does not declare in a reasonable time; in which case it is usual for the defendant's attorney to enter a rule for the plaintiff to declare, after which a *non pros* may be entered. A *nolle prosequi* is esteemed a voluntary confession, that the plaintiff has no cause of action: and therefore if a plaintiff enter his *nolle prosequi*, he shall be amerced; and if an informer cause the same to be entered, the defendant shall have costs.

NOMADES,

NOMADES, a name given, in antiquity, to feveral nations or people whofe whole occupation was to feed and tend their flocks; and who had no fixed place of abode, but were conftantly fhifting, according to the conveniencies of pafturage.—The word comes from the Greek νεμω, *pafco*, "I feed."

The moft celebrated among the Nomades were thofe of Africa, who inhabited between Africa, properly fo called, to the eaft, and Mauritania to the weft. They are alfo called *Numidæ*, or *Numidians*.—Salluft fays, they were a colony of Perfians brought into Africa with Hercules.

The Nomades of Afia inhabited the coafts of the Cafpian Sea.—The Nomades of Scythia were the inhabitants of Little Tartary; who ftill retain the ancient manner of living.

NOMARCHA, in antiquity, the governor or commander of a nome, or nomos.—Egypt was anciently divided into feveral regions or quarters, called *nomes*, from the Greek νομος, taken in the fenfe of a divifion; and the officer who had the adminiftration of each *nome*, or *nomos*, from the king, was called *monarcha*, from νομος and αρχη, "command."

NOMBRE-DE-DIOS, a town of Mexico, in the province of Darien, a little to the eaftward of Porto-Bello. It was formerly a famous place; but it is now abandoned, on account of its unhealthy fituation. W. Long. 78. 35. N. Lat. 9. 43.

NOMBRIL POINT, in heraldry, is the next below the fefs point, or the very centre of the efcutcheon.

Suppofing the efcutcheon divided into two equal parts below the fefs, the firft of thefe divifions is the nombril, and the lower the bafe.

NOME, or NAME, in algebra, denotes any quantity with a fign prefixed or added to it, whereby it is connected with fome other quantity, upon which the whole becomes a binomial, trinomial, or the like. See ALGEBRA.

NOMENCLATOR, in Roman antiquity, was ufually a flave who attended upon perfons that ftood candidates for offices, and prompted or fuggefted to them the names of all the citizens they met, that they might court them and call them by their names, which among that people was the higheft piece of civility.

NOMENCLATORS, among the botanical authors, are thofe who have employed their labours about fettling and adjufting the right names, fynonyms, and etymologies of names, in regard to the whole vegetable world.

NOMENCLATURE, NOMENCLATURA, a catalogue of feveral of the more ufual words in any language, with their fignifications, compiled in order to facilitate the ufe of fuch words to thofe who are to learn the tongue: fuch are our Latin, Greek, French, &c. Nomenclatures.

NOMENEY, a town of Germany, in the duchy of Lorrain, fituated on the river Seille, 15 miles north of Nancy.

NOMINALS, or NOMINALISTS, a fect of fchool-philofophers, the difciples and followers of Occam, or Ocham, an Englifh cordelier, in the 14th century. They were great dealers in words, whence they were vulgarly denominated *Word-fellers*; but had the denomination of *Nominalifts*, becaufe that, in oppofition to the *Realifts*, they maintained, that words, and not things, were the object of dialectics.

NOMINATIVE, in grammar, the firft CASE of NOUNS which are declinable.

The fimple pofition, or laying down of a noun, or name, is called the *nominative cafe*; yet it is not fo properly a cafe, as the matter or ground, whence the other cafes are to be formed, by the feveral changes and inflections given to this firft termination. Its chief ufe is to be placed in difcourfe before all verbs, as the fubject of the propofition or affirmation.

NONAGE, in law, generally fignifies all the time a perfon continues under the age of 21; but, in a fpecial fenfe, it is all the time that a perfon is under the age of 14.

NON-CAPE, a promontory on the weft coaft of Africa, oppofite to the Canary iflands. W. Long. 12. 0. N. Lat. 44. 28.

NONCONFORMISTS, thofe who refufe to join the eftablifhed worfhip.

Nonconformifts, in England, are of two forts. Firft, fuch as abfent themfelves from divine worfhip in the eftablifhed church through total irreligion, and attend the fervice of no other perfuafion. Thefe, by the ftat. 1 Eliz. c. 2. 23 Eliz. c. 1. and 3 Jac. I. c. 4. forfeit one fhilling to the poor every Lord's-day they fo abfent themfelves, and 20l. to the king if they continue fuch default for a month together. And if they keep any inmate thus irreligioufly difpofed in their houfes, they forfeit 10l. *per* month. *Blackft. Comment.*

The fecond fpecies of nonconformifts are thofe who offend through a miftaken or perverfe zeal. Such were efteemed, by the Englifh laws enacted fince the time of the Reformation, to be Papifts and Proteftant diffenters: both of which were fuppofed to be equally fchifmatics, in not communicating with the national church; with this difference, that the Papifts divided from it upon material, though erroneous, reafons; but many of the diffenters upon matters of indifference, or, in other words, upon no reafon at all. "Yet certainly (fays Sir William Blackftone) our anceftors were miftaken in their plans of compulfion and intolerance. The fin of fchifm, as fuch, is by no means the object of temporal coercion and punifhment. If, through weaknefs of intellect, through mifdirected piety, through perverfenefs and acerbity of temper, or (which is often the cafe) through a profpect of fecular advantage in herding with a party, men quarrel with the ecclefiaftical eftablifhment, the civil magiftrate has nothing to do with it; unlefs their tenets and practice are fuch as threaten ruin or difturbance to the ftate. He is bound indeed to protect the eftablifhed church: and if this can be better effected by admitting none but its genuine members to offices of truft and emolument, he is certainly at liberty fo to do; the difpofal of offices being matter of favour and difcretion. But, this point being once fecured, all perfecution for diverfity of opinions, however ridiculous or abfurd they may be, is contrary to every principle of found policy and civil freedom. The names and fubordination of the clergy, the pofture of devotion, the materials and colour of the minifter's garment, the joining in a known or unknown form of prayer, and other matters of the fame kind, muft be left to the option of every man's private judgment.

Noncon-formifts.

Blackft. Comment.

" With regard therefore to *Proteftant diffenters,* although the experience of their turbulent difpofition in former times occafioned feveral difabilities and reftrictions (which I fhall not undertake to juftify) to be laid upon them by abundance of ftatutes; yet at length the legiflature, with a true fpirit of magnanimity, extended that indulgence to thefe fectaries, which they themfelves, when in power, had held to be countenancing fchifm, and denied to the church of England. The penalties are conditionally fufpended by the ftatute 1 W. & M. ft. 1. c. 18. " for exempting their Majefties Proteftant fubjects, diffenting from the church of England, from the penalties of certain laws," commonly called the *toleration act;* which declares, that neither the laws above-mentioned, nor the ftatutes 1 Eliz. c. 2. § 14. 3 Jac. I. c. 4. & 5. nor any other penal laws made againft Popifh recufants (except the teft-acts) fhall extend to any diffenters, other than Papifts and fuch as deny the Trinity: provided, 1. That they take the oaths of allegiance and fupremacy, (or make a fimilar affirmation, being Quakers), and fubfcribe the declaration againft Popery. 2. That they repair to fome congregation certified to, and regiftered in the court of the bifhop or archdeacon, or at the county-feffions. 3. That the doors of fuch meeting-houfe fhall be unlocked, unbarred, and unbolted; in default of which, the perfons meeting there are ftill liable to all the penalties of the former acts. Diffenting teachers, in order to be exempted from the penalties of the ftatutes 13 & 14 Car. II. c. 4. 17 Car. II. c. 2. and 22 Car. II. c. 1. are alfo to fubfcribe the articles of religion mentioned in the ftatute 13 Eliz. c. 12. (viz. thofe which only concern the confeffion of the true Chriftian faith, and the doctrine of the facraments), with an exprefs exception of thofe relating to the government and powers of the church, and to infant-baptifm. And by ftatute 10 Ann. c. 2. this toleration is ratified and confirmed; and it is declared, that the faid act fhall at all times be inviolably obferved for the exempting fuch Proteftant diffenters as are thereby intended, from the pains and penalties therein mentioned. Thus, though the offcence of nonconformity is by no means univerfally abrogated, it is fufpended, and ceafes to exift with regard to thefe Proteftant diffenters, during their compliance with the conditions impofed by the act of toleration: and, under thefe conditions, all perfons, who will approve themfelves no Papifts or oppugners of the Trinity, are left at full liberty to act as their confciences fhall direct them in the matter of religious worfhip. And if any perfon fhall wilfully, malicioufly, or contemptuoufly difturb any congregation, affembled in any church or permitted meeting-houfe, or fhall mifufe any preacher or teacher there, he fhall (by virtue of the fame ftatute) be bound over to the feffions of the peace, and forfeit 20 l. But by ftatute 5 Geo. I. c. 4. no mayor or principal magiftrate muft appear at any diffenting meeting with the enfigns of his office, on pain of difability to hold that or any other office: the legiflature judging it a matter of propriety, that a mode of worfhip, fet up in oppofition to the national, when allowed to be exercifed in peace, fhould be exercifed alfo with decency, gratitude, and humility. Neither doth the act of toleration extend to enervate thofe claufes of the ftatutes 14 & 13 Car. II. c. 4. & 17 Car. II. c. 2. which prohibit (upon pain of fine and imprifonment) all perfons from teaching fchool, unlefs they be licenfed by the ordinary, and fubfcribe a declaration of conformity to the liturgy of the church, and reverently frequent divine fervice *eftablifhed* by the laws of this kingdom.

Noncon-formifts.

" As to *Papifts,* what has been faid of the Proteftant diffenters would hold equally ftrong for a general toleration of them; provided their feparation was founded only upon difference of opinion in religion, and their principles did not alfo extend to a fubverfion of the civil government. If once they could be brought to renounce the fupremacy of the Pope, they might quietly enjoy their feven facraments; their purgatory, and auricular confeffion; their worfhip of relics and images; nay, even their tranfubftantiation. But while they acknowledge a foreign power, fuperior to the fovereignty of the kingdom, they cannot complain if the laws of that kingdom will not treat them upon the footing of good fubjects.

" The following are the laws that have been enacted againft the Papifts; who may be divided into three claffes, perfons profeffing Popery, Popifh recufants convict, and Popifh priefts. 1. Perfons profeffing the Popifh religion, befides the former penalties for not frequenting their parifh-church, are difabled from taking any lands either by defcent or purchafe, after 18 years of age, until they renounce their errors; they muft at the age of 21 regifter their eftates before acquired, and all future conveyances and wills relating to them; they are incapable of prefenting to any advowfon, or granting to any other perfon any avoidance of the fame; they may not keep or teach any fchool under pain of perpetual imprifonment; and, if they willingly fay or hear mafs, they forfeit the one 200, the other 100 merks, and each fhall fuffer a year's imprifonment. Thus much for perfons who, from the misfortune of family-prejudices, or otherwife, have conceived an unhappy attachment to the Romifh church from their infancy, and publicly profefs its errors. But if any evil induftry is ufed to rivet thefe errors upon them; if any perfon fends another abroad to be educated in the Popifh religion, or to refide in any religious houfe abroad for that purpofe, or contributes to their maintenance when there; both the fender, the fent, and the contributor, are difabled to fue in law or equity, to be executor or adminiftrator to any perfon, to take any legacy or deed of gift, and to bear any office in the realm; and fhall forfeit all their goods and chattels, and likewife all their real eftate for life. And where thefe errors are alfo aggravated by apoftacy or perverfion; where a perfon is reconciled to the fee of Rome, or procures others to be reconciled, the offence amounts to high-treafon. 2. Popifh recufants, convicted in a court of law of not attending the fervice of the church of England, are fubject to the following difabilities, penalties, and forfeitures, over and above thofe beforementioned. They are confidered as perfons excommunicated; they can hold no office or employment; they muft not keep arms in their houfes, but the fame may be feized by the juftices of the peace; they may not come within 10 miles of London, on pain of 100 l.; they can bring no action at law or fuit in equity; they are not permitted to travel above five miles from home, unlefs by licenfe,

Nonconformiſts.

cenſe, upon pain of forfeiting all their goods; and they may not come to court under pain of 100 l. No marriage or burial of ſuch recuſant, or baptiſm of his child, ſhall be had otherwiſe than by the miniſters of the church of England, under other ſevere penalties. A married woman, when recuſant, ſhall forfeit two thirds of her dower or jointure, may not be executrix or adminiſtratrix to her huſband, nor have any part of his goods; and during the coverture may be kept in priſon, unleſs her huſband redeems her at the rate of 10 l. a month, or the third part of all his lands. And laſtly, as a feme-covert recuſant may be impriſoned, ſo all others muſt, within three months after conviction, either ſubmit and renounce their errors, or, if required ſo to do by four juſtices, muſt abjure and renounce the realm: and if they do not depart, or if they return without the king's licence, they ſhall be guilty of felony, and ſuffer death as felons without benefit of clergy. There is alſo an inferior ſpecies of recuſancy, (refuſing to make the declaration againſt Popery enjoined by ſtatute 30 Car. II. ſt. 2. when tendered by the proper magiſtrate); which, if the party reſides within ten miles of London, makes him an abſolute recuſant convict; or, if at a greater diſtance, ſuſpends him from having any ſeat in parliament, keeping arms in his houſe, or any horſe above the value of 5 l. 3. Popiſh prieſts are in a ſtill more dangerous condition. By ſtatute 11 & 12 W. III. c. 4. Popiſh prieſts, or biſhops, celebrating maſs or exerciſing any part of their functions in England, except in the houſes of ambaſſadors, are liable to perpetual impriſonment. And by the ſtatute 27 Eliz. c. 2. any Popiſh prieſt, born in the dominions of the crown of England, who ſhall come over hither from beyond ſea, (unleſs driven by ſtreſs of weather and tarrying only a reaſonable time), or ſhall be in England three days without conforming and taking the oaths, is guilty of high treaſon: and all perſons harbouring him are guilty of felony without the benefit of clergy.

This is a ſhort ſummary of the laws againſt the Papiſts; of which the preſident Monteſquieu obſerves, that they are ſo rigorous, though not profeſſedly of the ſanguinary kind, that they do all the hurt that can poſſibly be done in cold blood. But in anſwer to this it may be obſerved, (what foreigners who only judge from our ſtatute-book are not fully apprized of) that theſe laws are ſeldom exerted to their utmoſt rigour: and indeed, if they were, it would be very difficult to excuſe them. For they are rather to be accounted for from their hiſtory, and the urgency of the times which produced them, than to be approved (upon a cool review) as a ſtanding ſyſtem of law. The reſtleſs machinations of the Jeſuits during the reign of Elizabeth, the turbulence and uneaſineſs of the Papiſts under the new religious eſtabliſhment, and the boldneſs of their hopes and wiſhes for the ſucceſſion of the queen of Scots, obliged the parliament to counteract ſo dangerous a ſpirit by laws of a great, and then perhaps neceſſary, ſeverity. The powder-treaſon, in the ſucceeding reign, ſtruck a panic into James I. which operated in different ways: it occaſioned the enacting of new laws againſt the Papiſts; but deterred him from putting them in execution. The intrigues of queen Henrietta in the reign of Charles I. the proſpect of a Popiſh ſucceſſor in that of Char. II. the aſſaſſination-plot in the reign of king William, and the avowed claim of a Popiſh pretender to the crown in ſubſequent reigns, will account for the extenſion of theſe penalties at thoſe ſeveral periods of our hiſtory." But now that all juſt fears of a pretender may be ſaid to have vaniſhed; and the power and influence of the pope has become feeble, ridiculous, and deſpicable, not only in Britain, but in almoſt every kingdom of Europe; and as in fact the Britiſh Catholics ſolemnly diſclaim the dangerous principles aſcribed to them †; the Britiſh legiſlature, giving way to that liberality of ſentiment becoming Proteſtants, have lately repealed the moſt rigorous of the above edicts, *viz.* The puniſhment of Popiſh prieſts or Jeſuits who ſhould be found to teach or officiate in the ſervices of that church; which acts were felony in foreigners, and high treaſon in the natives of this kingdom:—The forfeitures of Popiſh heirs, who had received their education abroad; and whoſe eſtates went to the next Proteſtant heir:—The power given to the ſon, or other relation, being a Proteſtant, to take poſſeſſion of the father's or other relation's eſtate, during the life of the real proprietor:—And the debarring Papiſts from the power of acquiring any legal property by purchaſe.—In propoſing the repeal of theſe penalties, it was obſerved, That, beſides that ſome of them had now ceaſed to be neceſſary, others were at all times a diſgrace to humanity. The impriſonment of a Popiſh prieſt for life, only for officiating in the ſervices of his religion, was horrible in its nature: And although the mildneſs of government had hitherto ſoftened the rigour of the law in the practice, it was to be remembered that the Roman Catholic prieſts conſtantly lay at the mercy of the baſeſt and moſt abandoned of mankind—of common informers; for on the evidence of any of theſe wretches, the magiſterial and judicial powers were of neceſſity bound to enforce all the ſhameful penalties of the act. Others of theſe penalties held out the moſt powerful temptations for the commiſſion of acts of depravity, at the very thought of which our nature recoils with horror: They ſeemed calculated to looſen all the bands of ſociety; to diſſolve all civil, moral, and religious obligations and duties, to poiſon the ſources of domeſtic felicity, and to annihilate every principle of honour. The encouragement given to children to lay their hands upon the eſtates of their parents, and the reſtriction which debars any man from the honeſt acquiſition of property, need only to be mentioned to excite indignation in an enlightened age.

† See their loyal Addreſs to the throne, May 1. 1778, as inſerted in the Magazines or Annual Regiſter for that year.

In order the better to ſecure the Engliſh eſtabliſhed church againſt perils from non-conformiſts of all denominations, infidels, Turks, Jews, heretics, Papiſts, and ſectaries, there are, however, two bulwarks erected; called the *corporation* and *teſt acts*: By the former of which, no perſon can be legally elected to any office relating to the government of any city or corporation, unleſs, within a twelvemonth before, he has received the ſacrament of the Lord's ſupper according to the rights of the church of England; and he is alſo enjoined to take the oaths of allegiance and ſupremacy at the ſame time that he takes the oath of office: or, in default of either of theſe requiſites, ſuch election ſhall be void. The other, called the *teſt act*, directs all officers civil and military to take the oaths and make the declaration againſt tranſubſtantiation, in any of

of the king's courts at Weftminfter, or at the quarter-feffions, within fix calendar months after their admiffion; and alfo within the fame time to receive the facrament of the Lord's fupper, according to the ufage of the church of England, in fome public church immediately after divine fervice and fermon, and to deliver into court a certificate thereof figned by the minifter and church-warden, and alfo to prove the fame by two credible witneffes; upon forfeiture of 500l. and difability to hold the faid office. And of much the fame nature with thefe is the ftatute 7 Jac. I. c. 2. which permits no perfons to be naturalifed or reftored in blood, but fuch as undergo a like teft: which teft having been removed in 1753, in favour of the Jews, was the next feffion of parliament reftored again with fome precipitation.

NON-*Naturals*, in medicine, fo called, becaufe by their abufe they become the caufes of difeafes.

Phyficians have divided the non-naturals into fix claffes, viz. the air, meats and drinks, fleep and watching, motion and reft, the paffions of the mind, the retentions and excretions. See MEDICINE, n° 147, &c.

NON *Obftante*, *(notwithftanding,)* a claufe frequent in ftatutes and letters-patent, importing a licence from the king to do a thing, which at common law might be lawfully done, but being reftrained by act of parliament cannot be done without fuch licence.

NON *Pros*. See NOLLE *Profequi*.

NON-*Suit*, fignifies the dropping of a fuit or action, or a renouncing thereof by the plaintiff or defendant; which happens moft commonly upon the difcovery of fome error in the plaintiff's proceedings when the caufe is fo far proceeded in, that the jury is ready at the bar to deliver in their verdict.

NONES, (NONÆ,) in the Roman kalendar, the fifth day of the months January, February, April, June, Auguft, September, November, and December; and the feventh of March, July, and October. March, May, July, and October, had fix days in their nones; becaufe thefe alone, in the ancient conftitution of the year by Numa, had 31 days a-piece, the reft having only 29, and February 30: but when Cæfar reformed the year, and made other months contain 31 days, he did not allot them fix days of nones.

NONIUS (Peter), in Spanifh *Nunes*, a learned Portuguefe, and one of the ableft mathematicians of the 16th century, was born at Alcacer. He was preceptor to Don Henry, king Emmanuel's fon, and taught the mathematics in the univerfity of Coimbra. He publifhed the following works, by which he gained great reputation: 1. *De arte navigandi*. 2. *Annotationes in theorias planetarum Purbachii*; which are greatly efteemed. 3. A treatife *De crepufculis*. 4. A treatife on algebra. It is obferved in Furetiere's dictionary, that Peter Nonius, in 1530, firft invented the angles of 45 degrees made in every meridian, and that he called them *rhumbs* in his language, and calculated them by fpherical triangles. Nonius died in 1577, aged 80.

NONIUS (Marcellus), a grammarian and Peripatetic philofopher, born at Tivoli, wrote a treatife, intitled *De proprietate fermonum*. This author is only valuable for his giving fragments of ancient authors that are nowhere elfe to be found. The above treatife was printed at Paris in 1614, with notes.

NONNIUS, or NONIUS (Lewis), a learned phyfician of Antwerp in the 17th century, wrote feveral works which are efteemed; the principal of which are, 1. An excellent treatife intitled *Ichthyophagia, five de Pifcium efu*. 2. *Hifpania*; which is of great ufe in underftanding the ancient geography of Spain. 3. A commentary on the medals of Greece, and thofe of Julius Cæfar, Auguftus, and Tiberius, in folio: it contains Goltzius's two works on the fame fubject. 4. A commentary on Goltzius's account of Greece, the iflands, &c. 5. Poems, &c.

NONNUS, a Greek poet of the 5th century, and native of Panopilis in Egypt, was the author of an heroic poem in 48 books, intitled *Dionyfiacorum*, and a paraphrafe in verfe of St John's Gofpel, which may ferve as a commentary upon it.

NORDEN (Frederic Lewis), an ingenious traveller and naval officer in the Danifh fervice, was born at Gluckftadt in Holftein in the year 1708. He was well fkilled in mathematics, fhip-building, and efpecially in architecture; and in 1732 obtained a penfion to enable him to travel for the purpofe of ftudying the conftruction of fhips, particularly the galleys and other rowing veffels ufed in the Mediterranean. He fpent near three years in Italy, and Chriftian VI. being defirous of obtaining a circumftantial account of Egypt, Mr Norden at Florence received an order to extend his travels to that country. How he acquitted himfelf in this commiffion, appears from his Travels into Egypt and Nubia, printed at Copenhagen in folio, 1756; and which were foon after tranflated into Englifh by Dr Peter Templeman. In the war between England and Spain, Mr Norden, then a captain in the Danifh navy, attended count Ulric Adolphus, a fea-captain, to England; and they went out volunteers under Sir John Norris, and afterwards under Sir Chaloner Ogle. During his ftay in London, Mr Norden was made a fellow of the royal fociety, and gave the public drawings of fome ruins and coloffal ftatues at Thebes in Egypt; with an account of the fame, in a letter to the royal fociety, 1741. His health at this time was declining; and taking a tour to France, he died at Paris in 1742.

NORFOLK, a county of England, fo called from its northern fituation in refpect of Suffolk, is bounded on the eaft and north by the German ocean; on the fouth by Suffolk, from which it is parted by the rivers Waveney, and the Leffer Oufe; and on the weft it is feparated from Cambridgefhire by the Greater Oufe, and from a fmall part of Lincolnfhire by the wafhes. According to Templeman, it extends in length 57 miles, in breadth 35, and 140 in circumference. It contains an area of 1426 fquare miles, one city, 32 market-towns, 711 villages, according to the book of rates; though fome make them 1500, and 236000 inhabitants, as fome have it, and 283000, according to others. It is divided into 31 hundreds, 164 vicarages, and 660 parifhes.

The air differs in different parts of the county, according to the foil, which in fome parts is marfhy, efpecially on the fea-coaft, and there the air is foggy and unwholefome: in others it is clayey and chalky, poor, lean, and fandy; and there the air is good. The county is almoft all champaign, except in fome places, where

where rife gentle hills. The marfh-lands yield rich pafture for cattle; the clay-grounds peafe, rye, and barley; and the fandy-heaths feed vaft flocks of large fheep, of which fome villages are faid to keep 4000 or 5000. Thefe heaths abound alfo in rabbits of a filver-grey colour. Walfingham is noted for producing the beft faffron. Great quantities of mackarel and herring are caught upon the coafts of this county, the former in the fpring, and the latter in September; efpecially at Yarmouth, where they are cured in a particular manner, and to great perfection. Wood and honey are alfo very plentiful in this fhire; and on the coafts jet and ambergreafe are fometimes found. The inhabitants are generally ftrong and active, fagacious and acute. That they are fo robuft, is the more to be wondered at, becaufe the common people live much on puddings, *Norfolk dumplings*. They are for the moft part in eafy circumftances, and were formerly very quarrelfome and litigious. In confequence of this difpofition, lawyers fwarmed among them to fuch a degree, that a ftatute was made fo early as the reign of Henry VI. to reftrain their number. The manufactures of the county, which is exceedingly populous, are chiefly woollen and worfted ftuffs, and ftockings, for which they are well fupplied with wool from the vaft flocks of fheep bred in it. It gives title of duke to the elder branch of the family of Howard, lies in the diocefe of Norwich, and fends twelve members to parliament, viz. two knights for the fhire, two citizens for Norwich, and two burgeffes for each of the boroughs of Lynn Regis, Great Yarmouth, Thetford, and Caftle-rifing.

The county is well watered, and fupplied with fifh by the rivers Yare, Thyrn, Waveney, the Greater and Leffer Oufe, and the Bure, befides rivulets. The Bure abounds in excellent perch, and the Yare has a fifh peculiar to it called the *ruffe*. The latter rifes about the middle of the county; and after being joined by the Waveney and Bure, falls into the fea at Yarmouth. At the equinoxes, efpecially the autumnal, the Oufe is fubject to great inundations, heing forced back by the fea that enters it with great fury.

Norfolk, a county of Virginia contiguous to North Carolina.

NORMANDY, a province of France, bounded on the north by the Englifh channel; on the eaft by Picardy and the ifle of France; on the fouth by Perche and Maine, and one part of Bretague; and on the weft by the ocean. It is about 150 miles in length, 80 in breadth, and 600 in circumference. It is one of the moft fertile, and brings in the largeft revenue of the kingdom. It abounds in all things except wine, but they fupply that defect by cyder and perry. There are vaft meadows, fat paftures, and the fea yields plenty of fifh. It contains iron, copper, and a great number of rivers and harbours. It carries on a great trade, is very populous, and comprehends a vaft number of towns and villages. It is divided into the Upper and Lower; the Upper borders upon Picardy, and the Lower upon Bretagne. The inhabitants are ingenious, and capable of underftanding arts and fciences, but they are very fond of law. The Normans, a people of Denmark and Norway, having entered France under Rollo, Charles the Simple ceded this country to them in 912, which from that time was called *Normandy*. Rollo was the firft duke, and held it as a fief of the crown of France, and feveral of his fucceffors after him, till William, the feventh duke, conquered England in 1066: from which time it became a province of England, till it was loft in the reign of king John, and re-united to the crown of France; but the Englifh ftill keep the iflands on the coafts of Normandy.

NORTH (Dudley, lord), the third baron of that accomplifhed family, was one of the fineft gentlemen in the court of king James; but, in fupporting that character, diffipated and gamed away the greateft part of his fortune. In 1645, he appears to have acted with the parliament; and was nominated by them to be adminiftrator of the admiralty, in conjunction with the great earls of Northumberland, Effex, Warwick, and others. He lived to the age of 85, the latter part of which he paffed in retirement; and wrote a fmall folio of mifcellanies, in profe and verfe, under this title, A Foreft promifcuous of feveral Seafons Productions, in four parts, 1659.

North (Dudley, lord) fon of the former, was made knight of the bath in 1616, at the creation of Charles prince of Wales; and fat in many parliaments, till fecluded by the prevailing party in that which condemned the king. From that period lord North lived privately in the country, and towards the end of his life entertained himfelf with books, and, as his numerous iffue required, with œconomy, on which he wrote a little tract, called *Obfervations and advices œconomical*, 12mo. His other works are, Paffages relating to the long parliament; The hiftory of the life of the lord Edward North, the firft baron of the family, addreffed to his eldeft fon; and a volume of effays.

North (Francis lord Guilford, lord-keeper of the great-feal in the reigns of Charles II. and James II.) was a third fon of the fecond Dudley lord North, baron of Kertling; and ftudied at St John's college in Cambridge, from whence he removed to Middle Temple. He acquired French, Italian, Spanifh, and Dutch; and became not only a good lawyer, but was well verfed in hiftory, mathematics, philofophy, and mufic. He was afterwards made the king's folicitor-general, and was chofen to reprefent the borough of Lynn in parliament. He fucceeded Sir Heneage Finch in the poft of attorney-general; and lord chief-juftice Vaughan, in the place of lord chief-juftice of the common-pleas. He was afterwards made keeper of the great-feal; and in 1683 was created a baron, by the title of *lord Guilford*. He died at his houfe at Wroxton in 1685. He wrote a philofophical effay on mufic; a paper on the gravitation of fluids, confidered in the bladders of fifhes, printed in Lowthorp's abridgment of the Philofophical Tranfactions; and fome other pieces.

North, one of the four cardinal points. See Pole.

North-*Cape*, the moft northerly promontory in Europe, on the coaft of Norway. E. Long. 21. 0. N. Lat. 78. 0.

North-*Foreland*, a cape or promontory of Kent, in the ifle of Thanet, four miles eaft of Margate. Between this and the South-Foreland are the Downs, through which all fhips pafs that are bound to or from the

North-Northamptonshire. the weft. E. Long. 1. 25. N. Lat. 51. 25.

NORTH-*Weft Paffage*, a paffage to the Pacific Ocean through Hudfon's Bay or Davis's Straits, and which hath been frequently attempted without fuccefs; notwithftanding which, many people are ftill of opinion that it is practicable.

NORTH-*Eaft Paffage*, a paffage to the Eaft Indies along the northern coafts of Afia, which, like the former, hath frequently been attempted, but hitherto without fuccefs. Concerning thefe paffages an opinion hath lately been revived by the hon. Daines Barrington, namely, that they ought to be attempted by the pole itfelf; and he hath no doubt of the poffibility of accomplifhing them by that means. See *North* POLE.

NORTHAMPTON, a town of England, capital of a county of the fame name, fituated in W. Long. 0. 55. N. Lat. 52. 15. According to Camden, it was formerly called *North-afandon*, from its fituation to the north of the river Nen, called anciently *Aufona*, by which and another leffer river it is almoft enclofed. Dr Gibfon fays, that the ancient Saxon annals called both it and Southampton fimply *Hamton;* and afterwards, to diftinguifh them, called the one, from its fituation, *Southamton*, and the other *Northamton;* but never *North-afandon*, Though it does not appear to be a place of very great antiquity, yet here was a caftle, and a church dedicated to St Andrew, built by Simon de Sancto Licio, commonly called *Senlez*, the firft earl of Northampton of that name. It is faid to have been burnt down during the Danifh depredations; but in the reign of St Edward it appears to have been a confiderable place. It was befieged by the barons in their war with king John; at which time that military work called *Hunfhill*, is fuppofed to have been raifed. In the time of Henry III. it fided with the barons, when it was befieged and taken by the king. Here the bloody battle was fought in which Henry VI. was taken prifoner; and feveral parliaments have been held in this town. It was entirely confumed by a moft dreadful fire in 1675; yet, by the help of liberal contributions from all parts of the kingdom, it hath fo recovered itfelf, that it is now one of the neateft and beft-built towns of the kingdom. Among the public buildings, which are all lofty, the moft remarkable are the church called *All-hallows*, the feffions and affize houfe, and the George inn, which belongs to the poor of the town. There was formerly a nunnery in the neighbouring meadows. A county-hofpital or infirmary has been lately built here, after the manner of thofe of Bath, London, Briftol, &c. It has a confiderable manufacture of fhoes and ftockings; and its fairs are noted for horfes both for draught and faddle; befides, it is a great thoroughfare for the north and weft roads. It gives title of *earl* to the family of Compton.

NORTHAMPTONSHIRE, a county of England, is fituated in the very heart of the kingdom: bounded on the eaft by the counties of Bedford and Huntingdon; on the fouth by thofe of Buckingham and Oxford; on the weft by Warwickfhire; and on the north by the counties of Leicefter, Rutland, and Lincoln, which are feparated from it by the Leffer Avon, and the Welland. Its greateft length is about 50 miles, its greateft breadth about 20, and its circumference about 130. It contains 33 parifhes; in which are one city, 11 market-towns, and 150,000 inhabitants. Nine members are returned to parliament for this county, viz. two knights for the fhire, two for the city of Peterborough, two for each of the towns of Northampton and Brockley, and one for Higham Ferrers. It lies in the Mid-land circuit, and the diocefe of Peterborough. As this county is dry, well cultivated, free from marfhes, except the fens about Peterborough, in the centre of the kingdom, and of courfe at a diftance from the fea, it enjoys a very pure and wholefome air. In confequence of this it is very populous, and fo full of towns and churches, that 30 fpires or fteeples may be feen in many places at one view; and even in the fens, the inhabitants feem to enjoy a good ftate of health, and to be little affected by the water which frequently overflows their grounds, efpecially in winter, but is never fuffered to remain long upon it. Its foil is exceeding fertile both in corn and pafturage; but it labours under a fcarcity of fuel, as it doth not produce much wood, and, by lying at a diftance from the fea, cannot be eafily fupplied with coal. Its commodities, befides corn, are fheep, wool, black cattle, and faltpetre; and its manufactures are ferges, tammies, fhalloons, boots, and fhoes. Befides many leffer brooks and ftreams, it is well watered by the rivers Nen, Welland, Oufe, and Leam; the three firft of which are large, and for the moft part navigable.

Northumberland.

NORTHUMBERLAND, the moft northerly county of England, and formerly a diftinct kingdom, is bounded on the north and weft by the river Tweed, which divides it from Scotland, the Cheviot-hills, and part of Cumberland; wafhed on the eaft by the German Ocean; and feparated from Durham on the fouth by the rivers Tyne and Derwent. This county, which gives the title of *duke* to a nobleman who married the daughter of Algernoon duke of Somerfet, whofe mother was heirefs of the Piercy family, extends about 50 miles in length from north to fouth, and above 40 from eaft to weft; and is remarkably populous, containing 11 market-towns, 280 villages, and 46 parifhes. The face of the country, efpecially towards the weft, is roughened with huge mountains, the moft remarkable of which are the Cheviot-hills, and the high ridge called *Ridefdale;* but the lands are level towards the fea-fide and the borders of Durham. The climate, like that of every other mountainous country in the neighbourhood of the fea, is moift and difagreeable: the air, however, is pure and healthy, as being well ventilated by breezes and ftrong gales of wind; and in winter mitigated by the warm vapours from the two feas, the Irifh and the German Ocean, between which it is fituated. The foil varies in different parts of the county. Among the hills it is barren; though it affords good pafture for fheep, which cover thofe mountains. The low country, when properly cultivated, produces plenty of wheat, and all forts of grain; and great part of it is laid out in meadow-lands and rich enclofures. Northumberland is well watered with many rivers, rivulets, and fountains: its greateft rivers are the Tweed and the Tyne. The Tyne is compofed of two ftreams called *South* and *North Tyne:* the firft rifes on the verge of Cumberland, near Alfton-moor; enters Northumberland,

land, running north to Haltwefel; then bends eafterly, and receiving the two fmall rivers Eaft and Weft Alon, unites above Hexham with the other branch, taking its rife at a mountain called *Fane-head* in the weftern part of the county, thence called *Tine-dale;* is fwelled in its courfe by the little river Shele; joins the Read near Billingham; and running in a direct line to the fouth-eaft, is united with the fouthern Tyne, forming a large river that wafhes Newcaftle, and falls into the German Ocean near Tinmouth.

In all probability the mountains of Northumberland contain lead-ore and other mineralized metals in their bowels, as they in all refpects refemble thofe parts of Wales and Scotland where lead mines have been found and profecuted. Perhaps the inhabitants are diverted from inquiries of this nature, by the certain profits and conftant employment they enjoy in working the coal-pits, with which this county abounds. The city of London, and the greateft part of England, are fupplied with fuel from thefe ftores of Northumberland, which are inexhauftible, enrich the proprietors, and employ an incredible number of hands and fhipping.

There are no natural woods of any confequence in this county; but many plantations belonging to the feats of noblemen and gentlemen, of which here is a great number. As for pot-herbs, roots, fallading, and every article of the kitchen-garden and orchard, they are here raifed in great plenty by the ufual means of cultivation; as are alfo the fruits of more delicate flavour, fuch as the apricot, peach, and nectarine. The fpontaneous fruits it produces in common with other parts of Great Britain, are the crab-apple, the floe or bullace, the hazle-nut, the acorn, hips, and haws, with the berries of the bramble, the juniper, wood-ftrawberries, cranberries, and bilberries.

Northumberland raifes a good number of excellent horfes and black cattle, and affords paftnre for numerous flocks of fheep; both the cattle and fheep are of a large breed, but the wool is coarfer than that which the more fouthern counties produce. The hills and mountains abound with a variety of game, fuch as red deer, foxes, hares, rabbits, heathcock, growfe, partridge, quail, plover, teal, and woodcock: indeed, this is counted one of the beft fporting counties in Great Britain. The fea and rivers are well ftocked with fifh; efpecially the Tweed, in which a vaft number of falmon is caught and carried to Tinmouth, where being pickled, they are conveyed by fea to London, and fold under the name of *Newcaftle falmon.*

The Northumbrians were anciently ftigmatized as a favage, barbarous people, addicted to cruelty, and inured to rapine. The truth is, before the union of the two crowns of England and Scotland, the borderers on each fide were extremely licentious and ungovernable, trained up to war from their infancy, and habituated to plunder by the mutual incurfions made into each kingdom; incurfions which neither truce nor treaty could totally prevent. People of a pacific difpofition, who propofed to earn their livelihood by agriculture, would not on any terms remain in a country expofed to the firft violence of a bold and defperate enemy: therefore the lands lay uncultivated, and in a great meafure deferted by every body but lawlefs adventurers, who fubfifted by theft and rapine. There was a tract 50 miles in length and 6 in breadth, between Berwick and Carlifle, known by the name of the *Debateable Land,* to which both nations laid claim, tho' it belonged to neither; and this was occupied by a fet of banditti who plundered on each fide, and what they ftole in one kingdom, they fold openly in the other: nay, they were fo dexterous in their occupation, that by means of hot bread applied to the horns of the cattle which they ftole, they twifted them in fuch a manner, that, when the right owners faw them in the market, they did not know their own property. Wardens were appointed to guard the marches or borders in each kingdom; and thefe offices were always conferred on noblemen of the firft character for influence, valour, and integrity. The Englifh border was divided into three marches, called the *eaft, weft,* and *middle marches;* the gentlemen of the country were conftituted deputy-wardens, who held march-courts, regulated the watches, difciplined the militia, and took meafures for affembling them in arms at the firft alarm: but in the time of peace between the two nations, they were chiefly employed in fuppreffing the infolence and rapine of the borderers. Since the union of the crowns, however, Northumberland is totally changed, both with refpect to the improvement of the lands, and the reformation of the inhabitants. The grounds, being now fecure from incurfion and infult, are fettled by creditable farmers, and cultivated like other parts of the kingdom. As hoftilities have long ceafed, the people have forgot the ufe of arms, and exercifed themfelves in the more eligible avocations of peace; in breeding fheep and cattle, manuring the grounds, working at the coal-pits, and in different branches of commerce and manufacture. In their perfons they are generally tall, ftrong, bold, hardy, and frefh-coloured; and though lefs unpolifhed than their anceftors, not quite fo civilized as their fouthern neighbours. The commonalty are well fed, lodged, and cloathed; and all of them remarkably diftinguifhed by a kind of *fhibboleth* or *whurle,* being a particular way of pronouncing the letter *R,* as if they hawked it up from the wind-pipe, like the cawing of rooks. In other refpects, the language they fpeak is an uncouth mixture of the Englifh and Scottifh dialects. There is no material diftinction between the fafhionable people of Northumberland, and thofe of the fame rank in other parts of the kingdom: the fame form of education will produce the fame effects in all countries. The gentlemen of Northumberland, however, are remarkable for their courage, hofpitality, and hard drinking.

A great number of Roman monuments have been found in this county; but the moft remarkable curiofity of that kind confifts in the remains of Hadrian's vallum and the wall of Severus See ADRIAN's *Wall,* and SEVERUS's *Wall.*

The moft noted towns in Northumberland, are Newcaftle, Morpeth, Alnwick, Berwick, Hexham, and North Shields.

NORWAY, a country of Europe, lying between the 57th and 72d degrees of north latitude, and between the 5th and 31ft degrees of longitude eaft from London; extending in length about 1000 miles, in a direct line from Lindefnaes, in the diocefe of Chri-

Chriſtianſand, to the North Cape, at the extremity of Finmark. Its breadth, from the frontiers of Sweden weſtward to Cape Statt, may amount to about 300 miles; but from thence the country becomes gradually narrower towards the north. On the ſouth it is bounded by the Schagen-rock, or Categate, the entrance into the Baltic; on the eaſt it is divided from Sweden by a long ridge of high mountains; and on the weſt and north it is waſhed by the northern ocean.

The coaſt of Norway, extending above 300 leagues, is ſtudded with a multitude of ſmall iſlands, affording habitation to fiſhermen and pilots, and paſture to a few cattle. They form an infinite number of narrow channels, and a natural barrier of rocks, which renders Norway inacceſſible to the naval power of its enemies. Attempts of this kind are the more dangerous, as the ſhore is generally bold, ſteep, and impending; ſo that cloſe to the rocks the depth of the ſea amounts to 100, 200, or 300 fathoms. The perils of the north ſea are moreover increaſed by ſudden ſtorms, ſunk rocks, violent currents, and dreadful whirlpools. The moſt remarkable vortex on this coaſt is called *Moſkoeſtrom*, from the ſmall iſland Moſke, belonging to the diſtrict of Lofoden in the province of Nordland. In time of flood, the ſtream runs up between Lofoden and Moſkoe with the moſt boiſterous rapidity; but in its ebb to the ſea, it roars like a thouſand cataracts, ſo as to be heard at the diſtance of many leagues. The ſurface exhibits different vortices; and if in one of theſe any ſhip or veſſel is abſorbed, it is whirled down to the bottom, and daſhed in pieces againſt the rocks. Theſe violent whirlpools continue without intervals, except for a quarter of an hour, at high and low water, in calm weather; for the boiling gradually returns as the flood or ebb advances. When its fury is heightened by a ſtorm, no veſſel ought to venture within a league of it. Whales have been frequently abſorbed within the vortex, and howled and bellowed hideouſly in their fruitleſs endeavours to diſengage themſelves. A bear, in attempting to ſwim from Lofoden to Moſkoe, was once hurried into this whirlpool, from whence he ſtruggled in vain for deliverance, roaring ſo loud as to be heard on ſhore; but, notwithſtanding all his efforts, he was borne down and deſtroyed. Large trees being abſorbed by the current, are ſucked down, and riſe again all ſhattered into ſplinters. There are three vortices of the ſame kind near the iſlands of Ferroe.

Norway is divided into the four governments of Aggerhus, Bergen, Drontheim, and Wardhus, beſides that of Bahus, which is now ſubject to Sweden. The province of Aggerhus comprehends the ſouth-eaſt part of Norway, extending in length about 300 miles. Its chief towns are Chriſtiania, the ſee of a biſhop, ſuffragan to the metropolitan ſee of Drontheim, where the ſovereign court of juſtice is held, in preſence of the viceroy and the governor of the province; Aggerhus, about 15 miles to the ſouthweſt of Chriſtiania; Frederickſhall, or Frederickſtadt, in the ſiege of which Charles XII. of Sweden loſt his life; Saltzberg, Tonſberg, Alleen, Hammar, and Hollen.

The government of Bergen lies in the moſt ſoutherly and weſterly part of Norway, including the city of the ſame name, which is an epiſcopal ſee, and a place of conſiderable trade; and Staff-hanger, ſituated in the bay of Buckenfior, about 80 miles to the ſouthward of Bergen. The third province, called *Drontheim* or *Trontheim*, extends about 500 miles along the coaſt; and is but thinly peopled. The chief town Drontheim, ſeated on a little gulph at the mouth of the river Nider, is the only Metropolitan ſee in Norway; and carries on a conſiderable trade in maſts, deals, tar, copper, and iron. Leetſtrand, Stronden, Scoerdale, Opdal, Romſdael, and Solendael, are likewiſe places of ſome traffic. The northern diviſion of Drontheim, called the *ſub-government of Salten*, comprehends the towns of Melanger and Scheen. The province of Wardhus, extending to the North Cape, and including the iſlands, is divided into two parts; namely, Finmark and Norwegian Lapland. The chief town, which is very inconſiderable, ſtands upon an iſland, called *Ward*, from whence the place and the government derive their name. The province of Bahus, though now yielded to the Swedes, is reckoned part of Norway, being a narrow track of land, about 90 miles in length, lying on the coaſt of the Categate.

The great chain of Norway mountains, running from north to ſouth, called indifferently *Rudfield*, *Sudefield*, *Skarsfield*, and *Scoreberg*, is known in different parts by other appellations; ſuch as *Dofrefield*, *Lamsfield*, *Sagnefield*, *Filefield*, *Halnefield*, *Hardangerfield*, *Joklefield*, *Byglefield*, *Hicklefield*, and *Hangfield*. The height and breadth of this extenſive chain likewiſe vary in different parts. To paſs the mountain Hardanger, a man muſt travel about 70 Engliſh miles whereas Filefield may be about 50 over. This laſt riſes about two miles and a half in perpendicular height; but Dofrefield is counted the higheſt mountain of Norway, if not of Europe. The river Drivane winds along the ſide of it in a ſerpentine courſe, ſo as to be met nine times by thoſe who travel the winter-road to the other ſide of the chain. The bridges are thrown over roaring cataracts, and but indifferently faſtened to the ſteep rocks on either ſide; ſo that the whole exhibits a very dreadful appearance, ſufficient to deter the traveller from hazarding ſuch a dangerous paſſage: for which reaſon, people generally chooſe the road over Filefield, which is much more tedious. This, however, is the poſt-road uſed by the king's carriages. The way is diſtinguiſhed by poſts fixed at the diſtance of 200 paces from each other, that, in ſnowy or dark weather, the traveller may not be bewildered. For the convenience of reſting and refreſhing, there are two mountain-ſtoves or houſes maintained on Filefield, as well as upon other mountains, at the expence of the public, and furniſhed with fire, light, and kitchen-utenſils. Nothing can be more diſmal and dreary than theſe mountains covered with eternal ſnow, where neither houſe, tree, nor living creature is to be ſeen, but here and there a ſolitary rein-deer, and perchance a few wandering Laplanders.

In travelling from Sweden to Nordenfields, there is only one way of avoiding this chain of mountains; and that is, where it is interrupted by a long deep valley, extending from Romſdale to Guldbrandſdale. In the year 1612, a body of 1000 Scots, commanded by Sinclair, and ſent over as auxiliaries to the Swedes, were put to the ſword in this defile, by the peaſants of Guld-

 Guldbrand, who never give quarter.

Befides this chain, there is a great number of detached mountains over all the country, that form valleys and ridges, inhabited by the peafants. Some of thefe are of incredible height, and others exhibit very remarkable appearances. In failing up Joering Creek on the left hand, the fight is aftonifhed with a groupe of mountains, refembling the profpect of a city, with old Gothic towers and edifices. In the parifh of Oerfkong is the high mountain Skopfhorn, the top of which reprefents the figure of a fortification, with regular walls and baftions. In the diftrict of Hilgeland appears a very high range of mountains, with feven pinnacles or crefts, known by the appellation of the *Seven Sifters*, difcernible a great way off at fea. To the fouthward of this range, though in the fame diftrict, rifes the famous mountain *Torghatten*, fo called becaufe the fummit refembles a man's head with a hat on, under which appears a fingle eye, formed by an aperture through the mountain, 150 ells high, and 3000 ells in length. The fun may be feen through this furprifing cavity, which is paffable by the foot of travellers. On the top of the mountain we find a refervoir of water, as large as a moderate fifh-pond: in the lower part is a cavern, through which a line 400 fathoms in length, being let down, did not reach the bottom. At Herroe in Sundmoer is another cavern called *Dolfteen*, fuppofed to reach under the fea to Scotland; which, however, is no more than an idle tradition. In the year 1750, two clergymen entered this fubterranean cavity, and proceeded a confiderable way, until they heard the fea dafhing over their heads: the paffage was as wide and high as an ordinary church, the fides perpendicular, and the roof vaulted. They defcended one flight of natural ftairs; but arriving at another, they were afraid to penetrate farther: they had gone fo far, however, that two candles were confumed in their progrefs and return. A cavern of a very curious nature, ferving as a conduit to a ftream of water, penetrates through the fides of the mountain Limur. In the diftrict of Rake, in the neighbourhood of Frederickfhall, are three cavities in a rock; one of which is fo deep, that a fmall ftone dropped down, does not reach the bottom in lefs than two minutes; and then the found it produces is pleafant and melodious, not unlike the found of a bell.

The vaft mountains and rugged rocks that deform the face of this country, are productive of numberlefs inconveniences. They admit of little arable ground: they render the country in fome parts impaffable, and every where difficult to travellers: they afford fhelter to wild beafts, which come from their lurking holes, and make terrible havock among the flocks of cattle: they expofe the fheep and goats, as well as the peafant, to daily accidents of falling over precipices: they occafion fudden torrents, and falls of fnow, which defcend with incredible impetuofity, and often fweep away the labours of the hufbandman; and they are fubject to dreadful difruptions, by which huge rocks are rent from their fides, and, hurling down, overwhelm the plains below with inevitable ruin. The peafants frequently build their houfes on the edge of a fteep precipice, to which they muft climb by ladders, at the hazard of their lives; and when a perfon dies, the corpfe muft be let down with ropes, before it can be laid in the coffin. In winter the mail is often drawn up the fides of fteep mountains. Even in the king's road, travellers are expofed to the frequent rifks of falling over thofe dreadful rocks; for they are obliged to pafs over narrow pathways, without rails or rifing on the fides, either fhored up with rotten pofts, or fufpended by iron bolts faftened in the mountains. In the narrow pafs of Naeroe is a remarkable way of this kind, which, above 600 years ago, the famous king Surre caufed to be made for the paffage of his cavalry; and even this would have been found impaffable by any other horfes than thofe of Norway, which are ufed to climb the rocks like goats. Another very difficult and dangerous road is that between Shogftadt and Vang in Volders, along the fide of a fteep mountain, in fome places fo narrow, that if two travellers on horfeback fhould meet in the night, they would find it impracticable either to pafs each other, or turn back. In fuch a cafe their lives could not be faved, unlefs one of them fhould alight, and throw his horfe headlong into the lake below, and then cling to the rock, until the other could pafs. When a fheep or goat makes a falfe ftep to the projection of a rock, from whence it can neither afcend nor defcend, the owner hazards his own life to preferve that of the animal. He directs himfelf to be lowered down from the top of the mountain, fitting on a crofs ftick, tied to the end of a long rope; and when he arrives at the place where the creature ftands, he faftens it to the fame cord, and it is drawn up with himfelf. Perhaps the other end of the rope is held by one perfon only; and there are fome inftances, in which the affiftant has been dragged down by the weight of his friend, fo that both have perifhed. When either man or beaft has had the misfortune to fall over very high precipices, they have not only been fuffocated by the repercuffion of the air, but their bodies have been always burft before they reached the ground. Sometimes entire crefts of rocks, many fathoms in length and breadth, have fallen down at once, creating fuch a violent agitation of the air, as feemed a prelude to the world's diffolution. At Steenbroc in Laerdale, a ftupendous mafs, larger than any caftle in the univerfe, appears to have been fevered and tumbled from the mountain in large, fharp, and ragged fragments, thro' which the river roars with hideous bellowing. In the year 1731, a promontory on Sundmoer, called *Rammersfield*, that hung over Nordal Creek, fuddenly gave way, and plunged into the water; which fwelled to fuch a degree, that the church of Strand, tho' half a league on the other fide of the bank, was overflowed: the creek, however, was not filled up; on the contrary, the fishermen declare they find no difference in the depth, which is faid to exceed 900 fathoms.

The remarkable rivers of Norway are thefe: The Nied, iffuing from Tydalen, on the borders of Sweden, runs weftward into the lake Selboe; and afterwards, turning to the northward, paffes by the city of Drontheim, to which it anciently gave the name of *Nideros* and *Nidrofia*: Sule Ely, that defcending from Sulefield, runs with a rapid courfe thro' Nordale into the fea: Gulen, which rifes near Sffarsfield in the north; and running 20 leagues weftward, thro' Aalen, Hlotaalen, Storen, and Melhuus, difcharges itfelf into the fea, about a league to the weft of Drontheim. In

Norway. In the year 1344, this river buried itſelf under ground: from whence it again burſt forth with ſuch violence, that the earth and ſtones thrown up by the eruption, filled the valley, and formed a dam; which, however, was ſoon broken and waſhed away by the force of the water. Divers churches, 48 farm-houſes, with 250 perſons, were deſtroyed on this occaſion. Otteroen, a large river, taking its riſe from the mountain Agde, runs about 30 leagues through Seeterdale and Efie, and diſembogues itſelf into the cataract of Wiland. The river Syre riſes near the mountain Lang, and winds its courſe thro' the vale of Syre into the lake of Lunde in the dioceſe of Chriſtianſand: thence it continues its way to the ſea, into which it diſcharges itſelf through a narrow ſtrait formed by two rocks. This contraction augments its impetuoſity, ſo that it ſhoots like an arrow into the ſea, in which it produces a very great agitation. Nid and Sheen are two conſiderable rivers, iſſuing out of Tillemark. Their water-falls have been diverted, with infinite labour, by canals and paſſages cut through the rocks, for the convenience of floating down the timber. Tyrefiord, or Dramme, is in the neighbourhood of Honifoſſe, joined by two rivers from Oedale and Hadeland, and diſembogues iſelf into the ſea near Bragneſs. Loven riſes in the higheſt part of Nummedal, and runs through Konſberg to the ſea near Laurwig. Glaamen is the largeſt river of Norway, diſtinguiſhed by the name of *Stor-Elvin*, or the *great river*. It derives its origin from the mountain Doſre, from whence it winds all along the plains of Oeſterdale and Soloe; then joins the Vorme, another conſiderable river riſing out of Mioes and Guldſbrandſdale. Theſe being joined, traverſe the lake Oeyeren; and thence iſſuing, run on to Sarp near Frederickſtadt.

Norway abounds with freſh-water lakes; the principal of which are, Ryſvand in Nordland, Snaaſen, Selboe, the Greater and Leſſer Mioes, Slirevand, Sperdille, Rand, Veſtn, Saren, Modum, Lund, Norſoe, Huidſoe, Fariſvand, and Oeyevand: all theſe are well ſtocked with fiſh, and navigable for large veſſels. Wars have been formerly carried on upon theſe inland ſeas; in ſome of which are ſmall floating iſlands, or parcels of earth with trees on them, ſeparated from the main land, and probably preſerved in compact maſſes by the roots of trees, ſhrubs and graſs, interwoven in the ſoil. In the year 1702, the family-ſeat of Borge, near Frederickſtadt, being a noble edifice, with lofty towers and battlements, ſuddenly ſunk into an abyſs 100 fathoms deep, which was inſtantaneouſly filled by a piece of water 300 ells in length, and about half as broad. Fourteen perſons, with 200 head of cattle, periſhed in this cataſtrophe, which was occaſioned by the river Glaamen precipitating itſelf down a water-fall near Sarp, and undermining the foundation. Of all the water-falls in Norway this of Sarp is the moſt dangerous for its height and rapidity. The current drives 17 mills; and roars with ſuch violence, that the water, being daſhed and comminuted among the rocks, riſes in the form of rain, where a beautiful rainbow may be always ſeen when the ſun ſhines. In ancient times this cataract was made uſe of for the execution of traitors and other malefactors: they were thrown down alive, that they might be daſhed in pieces on the points of rocks, and die in a dreadful commotion, analagous to thoſe they had endeavoured to excite in the community. Norway.

Great part of Norway is covered with foreſts of wood, which conſtitute the principal article of commerce in this country. They chiefly conſiſt of fir and pine, for which great ſums are received from foreigners, who export an immenſe number of maſts, beams, planks, and boards. Beſides, an incredible quantity is conſumed at home, in building houſes, ſhips, bridges, piles, moles, and fences; over and above the vaſt demand for charcoal to the founderies, and fewel for domeſtic uſes. Nay, in ſome places, the trees are felled for no other purpoſe but to clear the ground and to be burned into aſhes for manure. A good quantity of timber is yearly exported to Scotland and Spain: but this is inconſiderable when compared to the vaſt exports from Drammen, Frederickſhall, Frederickſtadt, Chriſtiania, Skeen, Arendal, Chriſtianſand, Chriſtian's-bay, and Drontheim. The maſts and large beams are floated down the rivers, and the reſt is divided into boards at the ſaw-mills. Theſe works ſupply a vaſt number of families with a comfortable ſubſtance. A tenth part of all ſawed timber belongs to his Daniſh majeſty, and makes a conſiderable branch of his revenue. The foreſts in Norway are ſo vaſt and thick, that the people ſeem to think there can never be a ſcarcity of wood, eſpecially as the ſoil is peculiarly adapted for the production of timber: they therefore deſtroy it with a waſteful hand; inſomuch that more wood rots in Norway than is burned in the whole kingdom of Denmark. The beſt timber grows in the provinces of Saltan, Helleland, Romſdale, Guldbrandſdale, Oeſterdale, Soloe, Valders, Hallingdale, Sognifiord, Tellemark, and the lordſhip of Nedene.

The climate of Norway is very different in different parts of the kingdom. At Bergen the winter is ſo moderate, that the ſeas are always open and practicable both to mariners and fiſhermen, except in creeks and bays, that reach far up into the country towards Filefield, when the keen north-eaſt wind blows from the land. On the eaſt ſide of Norway from the frontiers of Sweden to Filefield, the cold generally ſets in about the middle of October with great ſeverity, and laſts till the middle of April; during which interval the waters are frozen to a very conſiderable thickneſs, and the face of the country is covered with ſnow. In the year 1719, 7000 Swedes, who intended to attack Drontheim, periſhed in the ſnow on the mountain of Ruden or Tydel, which ſeparates Jempteland in Sweden from the dioceſe of Drontheim. A company of 200 Norwegian ſledgemen under major Emahus, found them all frozen to death on the ridge of the mountain, where they had been ſurpriſed by a ſtorm accompained with ſnow, hail, and extreme cold. Some of theſe unhappy victims appeared ſitting, ſome lying, and others kneeling in a poſture of praying. They had cut in pieces their muſkets, and burned the little wood they afforded. The generals Labarre and Zoega loſt their lives; and of the whole corps, conſiſting originally of 10,000, no more than 2500 ſurvived this dreadful cataſtrophe.

The cold is ſtill more intenſe in that part of Norway called *Finmark*, ſituated in the frigid zone near the

the polar circle. But if the winter is generally cold, the ſummer is often exceſſively hot, in Norway. The rays of the ſun are reverberated from the ſides of the mountains ſo as to render the weather cloſe and ſultry in the valleys; beſides the ſun's abſence below the horizon is ſo ſhort, that the atmoſphere and mountains have not time to cool. The heat is ſo great, that vegetation is remarkably quick. Barley is ſown, grows, ripens, and is reaped, in the ſpace of ſix weeks or two months.—The longeſt day at Bergen conſiſts of 19 hours; the ſun riſing at half an hour after two, and ſetting at half an hour after nine. The ſhorteſt day does not exceed ſix hours; for the ſun riſes at nine in the morning, and ſets at three in the afternoon. In the beginning of the year the daylight increaſes with remarkable celerity; and, at the approach of winter, decreaſes in the ſame proportion. In ſummer one may read and write at midnight by the light of the ſky. Chriſtian V. while he reſided at Drontheim, uſed to ſup at midnight without candles. In the diſtrict of Tromſen, at the extremity of Norway, the ſun is continually in view at midſummer. It is ſeen to circulate day and night round the north pole, contracting its orbit, and then gradually enlarging it, until at length it leaves the horizon. In the depth of winter, therefore, it is for ſome weeks inviſible; and all the light perceived at noon is a faint glimmering for about an hour and an half, proceeding from the reflection of the ſun's rays from the higheſt mountains. But the inhabitants of theſe provinces are ſupplied with other lights that enable them to follow their employments in the open air. The ſky being generally ſerene, the moonſhine is remarkably bright, and, being reflected from the mountains, illuminates the valleys. They are alſo aſſiſted by the Aurora Borealis, which is very frequent in the northern parts of Europe.

The air of Norway is generally pure and ſalubrious. On the ſea-coaſts, indeed, it is rendered moiſt by vapours and exhalations: but in the midland parts of the country, towards the mountains, the climite is ſo dry, that meal may be kept for many years without being worm eaten or damaged in the leaſt. The inhabitants have no idea of ſickneſs except what is occaſioned by exceſſes. It is ſaid that in the vale of Guldbrand the inhabitants live to ſuch extreme old age, that they become weary of life, and cauſe themſelves to be removed to a leſs ſalubrions climate, whereby they may have a chance of dying the ſooner. In conſumptions, however, the moiſt air on the ſea-ſide is found to be moſt agreeable to the lungs in reſpiration. Norway, being a mountanious country interſected by creeks, abounding with lakes, rivers, and ſnow, muſt be ſubject to frequent rains; and from ſudden thaws the inhabitants are ſometimes expoſed to terrible diſaſters. Vaſt maſſes of ſnow falling from precipices, overwhelm men, cattle, boats, houſes, nay even whole villages. About two centuries ago, a whole pariſh was covered and deſtroyed by an immenſe maſs of ſnow; and ſeveral domeſtic utenſils, as ſciſſars, knives, and baſons, have been at different times brought to light by a rivulet that runs under the ſnow, which has been gradually hardened and increaſed by repeated froſts and annual acceſſions.

The winds that chiefly prevail on the weſtern coaſt are thoſe that blow from the ſouth; whereas, on the other ſide of Fileſield, the winds that produce and continue the hard froſts are always northerly. In the ſummer, there is a kind of regular trade-wind on the coaſt of Bergen. In the forenoon the ſea begins to be cooled with a weſterly breeze, which continues till midnight. Then the land breeze begins from the eaſt, and blows till about ten in the morning. The coaſt is likewiſe ſubject to ſudden ſqualls and ſtorms. Hurricanes ſometimes riſe at ſea; and in theſe latitudes the phænomenon called a *water-ſpout* is not uncommon. One of theſe in the neighbourhood of Ferro is ſaid to have ſucked up with the water ſome laſts of herrings, which were afterwards dropped on Kolter, a mountain 1200 feet high.

The freſh-water of Norway is not very light or pure; but on the contrary is generally turbid, and depoſits a ſediment of adventitious matter, being ſometimes impregnated with oker, and particles of iron. Nevertheleſs it is agreeable to the taſte, and remarkably ſalubrious; as appears from the good health of the common people, who drink little or no other liquor.

The ſoil of Norway varies in different places according to the ſituation of rock or valley. The mountains here, as in every other country, are bare and barren; but the earth waſhed down from them by the rains, enriches and fertilizes the valleys. In theſe the ſoil generally conſiſts of black mould, ſand, loam, chalk and gravel, lying over one another in unequal ſtrata, and ſometimes in three or four ſucceſſions: the mould that lies uppermoſt is very fine and mellow, and fit to nouriſh all ſorts of vegetables. There is alſo clay found in different parts of this kingdom, of which the inhabitants begin to make earthen ware; but bricks and tiles are not uſed in building. The face of the country is in many places deformed by large ſwamps and marſhes, very dangerous to the traveller. Near Leeſſoe in the dioceſe of Chriſtianſand, a wooden cauſeway is extended near a mile over a moraſs; and if a horſe or any other animal ſhould make a falſe ſtep, he will ſink at once into the abyſs never to riſe again.

In a cold country like Norway, roughened with rocks and mountains, interſperſed with bogs, and covered with foreſts, we cannot expect to find agriculture in perfection. The ploughed lands, in reſpect to mountains, woods, meadows, and waſtes, do not exceed the proportion of 1 to 80; ſo that the whole country does not produce corn to maintain above half the number of its inhabitaats. The peaſants are diſcouraged from the practice of huſbandry by the frequency of accidents that ſeem peculiar to the climate. Even in the fruitful provinces of Guldbrandſdale, Oeſterdale, and Soloer, as well as in other places, when the corn appears in the moſt flouriſhing condition, the whole hope of the harveſt is ſometimes deſtroyed in one night by a ſudden froſt that nips the blade and extinguiſhes the vegetation. The kingdom is moreover viſited by ſome unfavourable years, in which the ſun ſeems to have loſt his genial power; the vegetables are ſtunted; the trees bud and bloom, yet bear no fruit; and the grain, though it riſes, will yet produce nothing but empty ears and ſtraw. This calamity, however, rarely occurs; and in general the cultivated parts of Norway yield plentiful crops of excellent

Norway. cellent rye, barley, and oats. The moft fruitful provinces are Nordland, Inderbarre, and Numedale, in the diocefe of Drontheim; Sognifiord, and Vaas in that of Bergen; Jedderen, Ryefylfk, Raabygdelag, and the lordfhip of Nedenes, in the diocefe of Chriftianfand; Hedemark in the diocefe of Aggerhuis; Hadeland, Toten, Romerige, Ringerige, and Guldbrandfdale: thefe territories not only produce grain enough for their own confumption, but likewife fupport their neighbours, and even fupply part of Sweden. Peafe are likewife propagated in this country, together with wheat, buck-wheat, hops, hemp and flax, but not to any confiderable advantage. The meadows are well ftored with pafturage for fheep and cattle, and the fields are productive of thofe vegetables which are common in other northern countries. Within thefe 50 years the people of Norway have beftowed fome attention on the culture of gardens, which in former times was fo neglected, that the cities and towns were fupplied with leeks, cabbage, and roots, from England and Holland. At prefent, however, the Norwegians raife their own culinary and garden roots and vegetables, which thrive there as well as in any other country. The fcurvy being a difeafe that prevails along the fea-coaft, Nature has fcattered upon it a variety of herbs efficacious in the cure of that diftemper; fuch as angelica, rofe-wort, gentian, creffes, trefoil, forrel, fcurvy-grafs, and a plant called *erich's grafs*, that grows in great plenty on the iflands of Northland; from whence the people of the continent fetch away boat-loads of it, to be preferved in barrels as a fuccedaneum for cabbage. There are alfo a few noxious vegetables little known in any country but Norway. In Guldbrandfale is a fpecies of grafs called *felfnape*; the root of which is fo poifonous, that any beaft which eats of it dies immediately, the belly burfting; nay, the carnivorous fowls that prey upon the carcafe of the beaft meet with the fame fate: children have been more than once poifoned by this root which neverthelefs is fometimes ufed externally as an amulet for arthritic diforders. Another vegetable pernicious to the cattle is the *Gramen offifragum Norwegienfe*, which is faid to mollify the bones of the cattle which feed upon it. Among the noxious plants of Norway we may alfo reckon the igle-grafs, fatal to fheep and goats; the tour-grafs, which affects horfes and cows with a fort of lethargy; and the plant torboe, or hifte-fpring, which produces nearly the fame effect on horfes, but is not at all prejudicial to cows, fheep, or any ruminating animals. The herb turte, not unlike angelica, operates nearly in the fame manner: yet the bears are faid to feed upon it with peculiar relifh; and when their hair begins to fall off by feeding upon this plant, they cure themfelves by eating the flefh of animals.

The common fruit-trees thrive tolerably well in Norway, the inhabitants of which have plenty of cherries, apples, and pears. Some kinds of plums attain maturity; which is feldom the cafe with grapes, apricots, and peaches. But even the apples and pears that ripen here are fummer-fruit; that which grows till the winter feldom coming to perfection. Great variety of agreeable berries are produced in different parts of this kingdom; fuch as the hagebar, a kind floes; an infufion of which in wine makes a pleafant cooling liquor; juniper-berries, corinths red and white, foelbar or fun-berries, rafpberries, goofeberries, blackberries, ftrawberries, &c. with many other fpecies that feem to be natives of Norway and Sweden. Among thofe are the tranæbar, the produce of the myrtillus repens, red and auftere, found in the fpring in perfection under the fnow, and much relifhed by by the reindeer; crakebeer, refembling bilberries, deemed a powerful antifcorbutic; agerbeer, larger and blacker than bilberries, of a pleafant acid, ripened by cold, and ufed as cherries for an infufion in wine: and finally tylte-beer, a red pleafant berry growing on a fhort ftem, with leaves like thofe of box: they are plucked off by handfuls, and fent to Denmark to be preferved for the table, where they are eaten by way of defert.

Of the trees that grow wild in Norway, the principal are the fir and the pine. The firft yield an annual revenue of 1,000,000 of rix-dollars, if we include the advantages refulting from the faw-mills and the mafts; one of which laft has been known to fell for 200 rix-dollars. The red fir-tree, which grows on the mountains, is fo rich in turpentine as to be almoft incorruptible. Some of the houfes belonging to the Norway peafants, built of this timber, are fuppofed to be above 400 years ftanding. In Guldbrandfdale the houfe is ftill to be feen ftanding in which king Olaf lodged five nights, above 700 years ago, when he travelled round the kingdom to convert the people to the Chriftian faith. Even 100 years after the trunk of the fir-tree has been cut down, the peafants burn the roots for tar, which is a very profitable commodity. In the fens, the refin of the fir-tree is by nature transformed into a fubftance which may be called *Norway frankincenfe*. The buds or pine-apples of this tree, boiled in ftale beer, make an excellent medicine for the fcurvy; lefs unpleafant to the tafte, though as efficacious, as tar-water. The pine-tree is more tall and beautiful than the fir, though inferior to it in ftrength and quality; for which reafon the planks of it are fold at an inferior price, and the peafants wafte it without remorfe. Norway likewife produces fome forefts of oak, which is found to be excellent for fhip-building. Here alfo grow plenty of elm-trees; the bark of which, being powdered, is boiled up with other food to fatten hogs, and even mixed by the poor among their meal: alfo the afh, from which the peafants diftill a balfam ufed in certain diforders, and which is ufed both externally and internally. Many other trees flourifh in this country, an enumeration of which would prove too tedious. Hazles grow here in fuch abundance, that 100 tons of the nuts are annually exported from Bergen alone.

A great diverfity of ftones is found in Norway, fome of which are of a furprifing figure. Several mountains confift chiefly of a brown pebble, which decays with age; nay, it fometimes diffolves, and drops into the fea, and, the cement being thus loofened, a terrible difruption enfues. In fome places the grey and black pebbles are intermixed with iron, copper, lead, filver, and gold. The ground, in certain diftricts, is covered with the fragments of rocks that have been precipitated from the fummits of mountains, and broken by their fall into innumerable fhivers. Between 20 and 30 years ago, in the neighbourhood of Bergen, a man

man was ſuddenly overwhelmed with ſuch a maſs, which formed a kind of vault around him. In this dreadful tomb he remained alive for ſeveral weeks. By his loud cries the place of his confinement was diſcovered; but it was found impoſſible to remove the huge ſtones by which he was incloſed. All that his friends could do for him was, to lower down meat and drink through ſome crevices; but at length the ſtones fell in, and cruſhed him to death.

In Norway are inexhauſtible quarries of excellent marble, black, white, blue, grey, and variegated; together with ſome detached pieces of alabaſter, ſeveral kinds of ſpar, chalk-ſtone, cement-ſtone, ſand-ſtone, mill-ſtone, baking-ſtone, ſlate, talc, magnets; and ſwine-ſtone, a production natural to Norway and Sweden, of a brown colour, fetid ſmell, in texture reſembling cryſtal, and deriving its name from a ſuppoſed efficacy in curing a diſtemper incident to ſwine. Here alſo is found the amianthus or ſtone-flax, of which incombuſtible cloth may be made. Norway, however, affords no flints, but plenty of pyrites or quartz, beautiful cryſtals, granates, amethyſts, agate, thunder-ſtones, and eagle-ſtones. Gold has formerly been found in a ſmall quantity in the dioceſe of Chriſtianſand, and coined into ducats. There is at preſent a very conſiderable ſilver-mine wrought at Kongſberg on the account and riſk of his Daniſh majeſty: the ore is ſurpriſingly rich, but interrupted in ſuch a manner, that the vein is often loſt. Many maſſes of pure ſilver have been found; and, among the reſt, one piece weighing 560 pounds, preſerved in the royal muſeum at Copenhagen. Such is the richneſs of theſe mines, that the annual produce amounts in value to a tun and an half in gold. About 5000 people are daily employed, and earn their ſubſiſtence, in thoſe ſtupendous works. Other ſilver-mines are proſecuted at Jarlſberg, but not to the ſame advantage; and here the ore is mixed with lead and copper. In many parts of this country copper-mines have been diſcovered; but the principal, and perhaps the richeſt in all Europe, is at Roraas, about 100 Engliſh miles from Drontheim. This work yields annually about 1100 ſhip-pounds of pure copper: the founderies belonging to it conſume yearly about 14,000 laſts of coal, and 500 fathoms of wood. The next in importance is the copper-work at Lykken, about 20 miles from Drontheim. A third mine is carried on at Indſet, or Quickne, at the diſtance of 30 miles from the ſame place; and here they precipitate the copper from its menſtruum, by means of iron. There is a fourth copper-work at Silboe, about 30 miles diſtant from Drontheim, though the leaſt conſiderable of the four. Other copper-mines of leſs note are worked in different parts of the kingdom. Iron is ſtill in greater plenty, and was the firſt metal wrought in this country. Many hundred thouſand quintals are annually exported, chiefly in bars, and part of it in ſtoves, pots, kettles, and cannon: the national profit ariſing from this metal is eſtimated at 300,000 rix-dollars. There is a ſpecies called *moor-iron*, found in large lumps among the moraſſes: of this the peaſants make their own domeſtic tools and utenſils, ſuch as knives, ſcythes, and axes. The lead found mixed in the ſilver ore is an article of ſmall importance in Norway; yet ſome mines of this metal have been lately opened in the diſtrict of Soloer, by the proprietors of the copper-work at Oudal. A vitriol work has been begun near Kongſberg: the mines yield great plenty of ſulphur; which, however, the Norwegians will not take the trouble to melt and depurate, becauſe immenſe quantities are found at a cheaper rate in the iſland of Iceland. Alum is found between the ſlate-flakes near Chriſtiana in ſuch plenty, that works have been ſet up for refining this mineral, though they have not yet brought it to any degree of tranſparency. His Daniſh majeſty has eſtabliſhed ſalt-works in the peninſula of Valoe, about ſix Engliſh miles from Tonſberg, where this mineral is extracted in large quantities from the ſea-water.

Beſides the animals common to other countries, Norway is ſaid to contain many of the uncommon and dubious kind; ſuch as the kraken, mermaid, ſea-ſerpent, &c. See theſe articles.

Many Daniſh, Engliſh, Scotch, Dutch, and German families have ſettled in Norway, and now form no inconſiderable part of the trading people: but the original inhabitants are the deſcendants of thoſe ferocious Normanni, who harraſſed almoſt all the coaſts of Europe with piratical armaments in the 8th, 9th, and 10th centuries. They ſpeak the ſame language that is uſed in Denmark, though their original tongue is the dialect now ſpoken in Iceland. They profeſs the Lutheran religion, under an archbiſhop eſtabliſhed at Drontheim, with four ſuffragans; namely, of Bergen, Staffanger, Hammer, and Chriſtiana. By the union of Calmar, the two kingdoms of Norway and Denmark were united under one monarch; and then the people of both nations enjoyed conſiderable privileges: but the Daniſh government is now become abſolute; and Norway is ruled deſpotically by a viceroy, who reſides in the capital, and preſides in the ſupreme court, to which appeals are made from the ſubordinate courts of judicature.

The Norwegians are generally well-formed, tall, ſturdy, and robuſt, brave, hardy, honeſt, hoſpitable, and ingenious: yet ſavage, raſh, quarrelſome, and litigious. The ſame character will nearly ſuit the inhabitants of every mountainous country in the northern climates. Their women are well-ſhaped, tall, comely, remarkably fair and obliging. The nobility of Norway have been chiefly removed by the kings of Denmark, in order to prevent faction, and oppoſition to the court; or are long ago degenerated into the rank of peaſants: ſome families, however, have been lately raiſed to that dignity. Every freeholder in Norway enjoys the right of primogeniture, and power of redemption; and it is very uſual to ſee a peaſant inhabiting the ſame houſe which has been poſſeſſed 400 years by his anceſtors. The *odels-gads*, or freehold, cannot be alienated by ſale or otherwiſe from the right heir, called *odels-mand:* if he is not able to redeem the eſtate, he declares his incapacity every 10th year at the ſeſſions; and if he, or his heirs, to the third generation, ſhould acquire wealth enough for that purpoſe, the poſſeſſor *pro tempore* muſt reſign his poſſeſſion.

The mountaineers acquire ſurpriſing ſtrength and dexterity by hard living, cold, laborious exerciſe, climbing rocks, ſkating on the ſnow, and handling arms, which they carry from their youth to defend themſelves againſt the wild beaſts of the foreſts. Thoſe who

dwell

Norway. dwell in the maritime parts of Norway exercife the employments of fifhing and navigation, and become very expert mariners.

The peafants of Norway never employ any handicraftfmen for neceffaries to themfelves and families: they are their own hatters, fhoe-makers, taylors, tanners, weavers, carpenters, fmiths, and joiners: they are even expert at fhip-building; and fome of them make excellent violins. But their general turn is for carving in wood, which they execute in a furprifing manner with a common knife of their own forging. They are taught in their youth to wreftle, ride, fwim, fkate, climb, fhoot, and forge iron. Their amufements confift in making verfes, blowing the horn, or playing upon a kind of guitarre, and the violin: this laft kind of mufic they perform even at funerals. The Norwegians have evinced their valour and fidelity in a thoufand different inftances. The country was always diftracted by inteftine quarrels, which raged from generation to generation. Even the farmers ftand upon their punctilio, and challenge one another to fingle combat with their knives. On fuch occafions they hook themfelves together by their belts, and fight until one of them is killed or mortally wounded. At weddings and public feafts they drink to intoxication, quarrel, fight, and murder generally enfues. The very common people are likewife paffionate, ambitious of glory and independence, and vain of their pedigree. The nobility and merchants of Norway fare fumptuoufly; but the peafant lives with the utmoft temperance and frugality, except at feftivals: his common bread is made of oat-meal, rolled into broad thin cakes, like thofe ufed in Scotland. In time of fcarcity, they boil, dry, and grind the bark of the fir-tree into a kind of flour which they mix with oat-meal: the bark of the elm-tree is ufed in the fame manner. In thofe parts where a fifhery is carried on, they knead the roes of cod with their oatmeal. Of thefe laft, mixed with barley-meal, they make hafty-pudding, and foup, enriched with a pickled herring or falted mackarel. Frefh fifh they have in plenty on the fea-coaft. They hunt and eat growfe, partridge, hare, red deer, and rein-deer. They kill cows, fheep, and goats, for their winter ftock: thefe they pickle, or fmoke, or dry for ufe. They make cheefe of their milk, and a liquor called *fyre* of their four whey: this they commonly drink mixed with water; but they provide a ftore of ftrong ale for Chriftmas, weddings, chriftenings, and other entertainments. From their temperance and exercife, joined to the purity and elafticity of their air, they enjoy good health, and often attain to a furprifing degree of longevity. Nothing is more common than to fee a hearty Norwegian turned of 100. In the year 1733, four couples danced before his Danifh majefty at Fredericks-hall: their ages, when joined, exceeded 800 years. Neverthelefs, the Norwegians are fubject to various difeafes; fuch as the fcab, the leprofy, the fcurvy, the catarrh, the rheumatifm, gout, and epilepfy. The drefs of the Norway peafants confifts of a wide loofe jacket made of coarfe cloath, with waiftcoat and breeches of the fame. Their heads are covered with flapped hats, or caps ornamented with ribbons. They wear fhoes without foles, and in the winter leathern bufkins. They have likewife fnow-fhoes and long fkates, with which they travel at a great pace, either on the land or ice. There is a corps of foldiers thus accoutred, who can out-march the fwifteft horfes. The Norwegian peafant never wears a neckcloth, except on extraordinary occafions: he opens his neck and breaft to the weather, and lets the fnow beat into his bofom. His body is girt round with a broad leathern belt, adorned with brafs plates, from which depends a brafs chain that fuftains a large knife, gimlet, and other tackle. The women are dreffed in clofe-laced jackets, having leathern girdles decorated with ornaments of filver. They likewife wear filver chains round their necks, to the ends of which are fixed gilt medals. Their caps and handkerchiefs are almoft covered with fmall plates of filver, brafs, and tin, large rings, and buttons. A maiden bride appears with her hair platted, and, together with her cloaths, hung full of fuch jingling trinkets. Norway.

The churches, public edifices, and many private houfes in Norway, are built of ftone: but the people in general live in wooden houfes, made of the trunks of fir and pine-tree laid upon each other, and joined by mortifes at the corners. Thefe are counted more dry, warm, and healthy, than ftone or brick buildings. In the whole diocefe of Bergen, one hardly fees a farm-houfe with a chimney or windows: they are generally lighted by a fquare hole in the top of the houfe, which lets in the light, and lets out the fmoke. In fummer this hole is left quite open: in the winter, it is covered with what they call a fiau; that is, the membrane of fome animal, ftretched upon a wooden frame that fits the hole, and tranfmits the rays of light. It is fixed or removed with a long pole, occafionally. Every perfon that enters the houfe, upon bufinefs or courtfhip, takes hold on this pole, according to ancient cuftom. The ceiling is about eight feet high in the middle; and, being arched like a cupola, the fmoke of the fire underneath rolls about, until it finds a vent at the hole, which is called *liur*. Under this opening ftands a thick table with benches, and an high feat at the upper end for the mafter of the family: he has likewife a fmall cupboard for his own ufe, in which he locks up his moft valuable effects. The boards of the roof are coated with the bark of birch-trees, which is counted incorruptible: this again is covered with turf, which yields a good crop of grafs for goats and fheep, and is often mowed as hay by the farmer.

The Norwegians carry on a confiderable trade with foreign nations. The duty on the produce of their own country exported, amounts annually to 100,000 rix-dollars. Thefe commodities are, copper wrought and unwrought; iron caft into cannon, ftoves, and pots, or forged into bars; lead, in fmall quantity; mafts, timber, deal-boards, planks, marble, millftones, herring, cod, ling, falmon, lobfters, flounders, cow-hides, goat-fkins, feal-fkins, the furs of bears, wolves, foxes, beavers, ermins, martens, &c. down, feathers, butter, tallow, train-oil, tar, juniper and other forts of berries, and nuts; falt, alum, glafs, vitriol, and pot-afhes. All other commodities and articles of luxury, the Norwegians import from different nations. The nature of the ground does not admit of much improvement in agriculture: neverthelefs, the farmers are not deficient in induftry, and fkill

to

to drain marfhes, and render the ground arable and fit for pafture. Many are employed in grazing and breeding cattle: but a much greater number is engaged in felling wood, floating timber, burning charcoal, and extracting tar from the roots of the trees which have been cut down; in the filver, copper, and iron mines; in the navigation and fifhery. A confiderable number of people earn a comfortable livelihood by hunting, fhooting, and bird-catching. Every individual is at liberty to purfue the game, efpecially in the mountains and commons: therefore every peafant is expert in the ufe of fire-arms; and there are excellent markfmen among the mountains, who make ufe of the bow to kill thofe animals whofe fkins, being valuable, would be damaged by the fhot of fire arms.

Norway can produce above 14,000 excellent feamen. The army of this country amounts to 30,000 effective men; and the annual revenue exceeds 800,000 rixdollars.

Norway-*Rat*, in zoology. See Mus.

NORWICH, the capital of the county of Norfolk in England, fituated in E. Long. 1. 26. N. Lat. 52. 40. It is fuppofed to have had its name, which fignifies "a caftle to the north," from its fituation in refpect of Caftor, the ancient Venta Icenorum, three or four miles to the fouth of it, out of whofe ruins it feems to have rifen. In its infancy, in the reign of Etheldred, it was plundered and burnt by Sueno the Dane, when he invaded England with a great army. Afterwards it recovered; and in the reign of Edward the Confeffor was a confiderable place, having 1320 burghers. But it fuffered again much in the reign of William I. by being the feat of a civil war, which Ralph, earl of the Eaft Angles, raifed againft that king. So much was it impaired by the fiege it then underwent, that there were fcarce 560 burghers left in it, as appears from Doomfday-book. From that time forward it began by little and little to recover, efpecially after bifhop Herbert tranflated the epifcopal fee hither from Thetford in the reign of William Rufus in 1096; and built a beautiful cathedral, of which he himfelf laid the firft ftone, with this infcription, *Dominus Herbertus pofuit primum lapidem, in Nomine Patris, Filii, & Spiritus Sancti*, Amen, i. e. "Lord (bifhop) Herbert laid the firft ftone, in the name of the Father, Son, and Holy Ghoft;" and by a licence from pope Pafchal, declared it the mother-church of Norfold and Suffolk. After this, as Malmfbury has it, it became a town famous for merchandize and the number of inhabitants. Yet it was miferably harraffed in the reign of Henry II. by Hugh Bigod, earl of Norfolk, who was an adherent of Henry's fon, called the *junior king*. In the time of Edward I. it was walled round by the citizens, who had prefented a petition to Parliament for liberty to do it. Henry IV. allowed them, inftead of bailiffs, which they had before, to elect a mayor yearly, and made the city a county of itfelf. In the year 1348, near 58 perfons were carried off by the plague; and in 1507, the city was almoft confumed by fire. For the flourifhing ftate to which the city is now arrived, they are much indebted to the Flemings, who fled hither from the tyranny of the duke of Alva and the inquifition, and taught them the manufacture of thofe ftriped and flowered damafks, camblets, druggets, black and white crape, for which the place is now fo noted, and which have been computed to yield fometimes 160,000 l. a-year. In the year 1583, the citizens, by the help of an engine, conveyed water thro' pipes to the higheft parts of the city, which is pleafantly feated along the fide of a hill, extending a mile and a half in length from north to fouth; but the breadth is much lefs, and it contracts itfelf by degrees towards the fouth. It is now one of the moft confiderable cities in Britain for wealth, populoufnefs, neat buildings, beautiful churches, of which it had once 50, but now about 30, and the induftry and civility of the inhabitants. The cathedral is a very venerable ftructure, with a curious roof, adorned with the hiftory of the Bible in little images, carved to the life, and a lofty fteeple 105 yards high. The wall of flint ftone, beautified with 40 towers and 12 gates, finifhed in 1309, is now much decayed. The city, though there is a great deal of wafte ground within the walls, was computed, upwards of 40 years ago, to contain 8000 houfes, and 50,000 inhabitants. Befides the cathedral already mentioned, the moft remarkable buildings are, the duke of Norfolk's houfe, one of the largeft in England; the caftle, which is now the county-gaol, and ftands in the heart of the city, with a deep moat round it, over which is a bridge of one very large arch; the Town-hall; the Guild-hall, formerly the church belonging to the monaftery of Black-Friars; the houfe of correction; the fhire-houfe, where the affizes are held; a lofty market-crofs, built after the manner of a piazza; the bifhop's palace; the king's fchool, founded by Edward VI. the boys to be nominated by the mayor for the time being, with the confent of the majority of aldermen. There having been formerly many thatched houfes, an order was made, that all houfes that fhould hereafter be built fhould be covered with tiles. The city is interfperfed with gardens, orchards, and trees, which make it both pleafant and healthful. It has four hofpitals, in which a great number of old men and women, boys and girls, are maintained; and a dozen charity-fchools. Here are two churches for the Dutch and French Flemings; who have particular privileges, and are very numerous. Some of the churches are thatched, and all of them crufted with flint ftone curioufly cut; which is the more wonderful, as Norwich ftands in a clay country, and has no flint within 20 miles of it. It is now governed by a mayor, recorder, fteward, two fheriffs, 24 aldermen, 60 common-council, with a town-clerk, fword-bearer, and other inferior officers. The mayor is chofen on May-day by the freemen, and fworn in on the Tuefday before Midfummer-eve. The fheriffs are alfo chofen annually, on the firft Tuefday in Auguft, one by the freemen, the other by the aldermen, and fworn in on Michaelmas-day. The freemen of the feveral wards chufe each their alderman. The common-council is chofen in Midlent. The mayor is a juftice of the peace and quorum, during his year (as are alfo the recorder and fteward) within the city and liberties; and after his mayoralty, he is a juftice during life. The trade and manufactures of the city are very confiderable. At Yarmouth they export large quantities of their manufactures, moft of which are fent to London, and import a great deal of wine, coal, fifh, oil, &c.

&c. All the city and country round are employed in the worſted manufacture, brought hither, as already obſerved, by the Flemings, in which they not only conſume the wool of their own county, in ſpinning, weaving, &c. but uſe many thouſand packs of yarn, which they receive from other parts of England, as far as Yorkſhire and Weſtmoreland. There are eight wardens of the weavers choſen annually, and ſworn to take care that there be no frauds committed in ſpinning, weaving, or dying the ſtuffs. It is computed that there are not leſs than 120,000 people employed in and about the city in the ſilk and woollen manufactures. Their markets are thought to be the greateſt in England, and furniſhed with a ſurpriſing plenty and variety of goods and proviſions. At a ſmall village to the north of the city called *St Faith's*, not leſs than 40,000 head of Scotch cattle are ſaid to be yearly bought up by the Norfolk graziers, and fattened in their meadows and marſhes. Its markets are on Wedneſday, Friday, and Saturday. It has a great number of fairs, and gives the title of earl to the duke of Norfolk.

NOSE, in anatomy; ſee there, nº 20, &c. The uſes of the noſe are, its giving us the ſenſe of ſmelling *; its ſerving in the great office of reſpiration, and in modelling voice; in receiving the abundant humours from the eyes, and in adding to the beauty of the face.

* See *Anatomy*, nº 404.

In Tartary, the greateſt beauties are thoſe who have the leaſt noſes. Ruybrock mentions the wife of the great Jenghiz Khan as a celebrated beauty, becauſe ſhe had only two holes for a noſe. In moſt other countries, China excepted, great noſes are in honour.

The Crim-Tartars break the noſes of their children while young, as thinking it a great piece of folly to have their noſes ſtand before their eyes.

NOSOLOGY, in medicine. See p. 4631—4643.

NOSTOCH, the name of a vegetable ſubſtance which ſeems to differ from moſt of the other bodies of that kind in ſeveral particulars. It is a ſubſtance of an irregular figure, of a greeniſh brown colour, and ſomewhat tranſparent. It trembles at the touch, in the manner of a jelly; but it does not melt when held in the hand. It has therefore ſomewhat of the characters of a vegetable leaf, but it has neither veins nor fibres. It is found in all ſorts of ſoils; but moſt frequently in ſandy ones, ſometimes on the gravel of garden walks, and moſt uſually makes its appearance after rain. It is found only in the ſummer-months; and retains its humidity and perfect figure as long as it is a moiſt ſeaſon, but immediately dries up and withers away on the ſun or the wind's affecting it. Many people have ſuppoſed this not to be a plant. It appears all on a ſudden, and, as it were, by a ſort of miracle, either from the earth or clouds; and ſome have called it *flower of earth*, others *flower of heaven*: and the obſcurity of its origin occaſioned its being held in great eſteem among the chemiſts; ſome of whom ſuppoſed it to contain an univerſal ſpirit, capable of converting other metals into gold. Mr Magnol and Mr Tournefort were the firſt authors who aſſerted its true origin, and ranged it among the plants. Its nature, however, was never perfectly diſcovered till Mr Reaumur took it under conſideration. He found that it was a leaf which naturally imbibed water in a very particular manner; that when it had enough of this liquor in it, it then appeared in its natural flouriſhing ſtate; and when it loſt this again, it became thin, wrinkled, and was not to be known for the ſame ſubſtance, or, indeed, ſcarce to be ſeen at all. Hence appears the reaſon of its ſuppoſed production and ſudden decay. If it has, ever ſo long, lain in the walks of a garden in its empty wrinkled ſtate, it is never taken notice of; but, on a ſhower of rain, it ſwells out into its jelly-like ſtate, and on the ſun's evaporating that moiſture it falls into its undiſtinguiſhable ſtate again; and theſe changes may affect the ſame plant alternately for many days together.

Mr Geoffroy imagined that he had found roots to the noſtoch; but Mr Reaumur poſitively aſſerts that it has none. He obſerved indeed, at certain times, on the ſurface of certain ſpecimens of this, a vaſt number of round tubercles of different ſizes, which appeared to be the ſeeds of the plant. Theſe he regularly ſowed in earthen pots of mould; and theſe produced young plants like the parent noſtoch: But even theſe were never diſcovered to have any appearance of roots; and to try farther whether they had any, Mr Reaumur turned all the plants bottom upwards, and they received no harm from it, but grew juſt as vigorouſly as before. If the noſtoch has truly no roots, as appears to be very evidently the caſe, it follows, that it imbibes its nouriſhment in the manner of ſea-plants, which imbibe the water at all their pores. It ſhould ſeem, that there are two ſpecies of this noſtoch: the one a plain, flat, leaf; the other curled, wrinkled, and variouſly undulated: and it is on this laſt that the fruits which produce the young plants are principally found. It may be, however, that the one of theſe may be the male and the other the female of the ſame ſpecies, as in many large plants; or poſſibly the being in the ſtate of fructification alone may make the difference.

NOSTRADAMUS (Michael), an able phyſician and famous aſtrologer, born at St Remy, a ſmall town, four leagues from Arles, in 1503. He ſtudied at Montpelier, and afterwards travelled to Toulouſe and Bourdeaux. At his return into Provence, he publiſhed, in 1555, his *Seven firſt prophetical centuries*. Theſe were ſo highly valued by the French king, Henry II. that he reſolved to ſee the author; and having cauſed him to be brought to him, gave him 200 golden crowns, and ſent him to ſee the princes his ſons at Blois. Charles IX. in paſſing through Provence, alſo gave him public marks of his eſteem. Noſtradamus publiſhed his three laſt Centuries in 1556; and died at Salon in 1566. He wrote other works, and after his death was collected an 11th and 12th Century from his writings. The following diſtich, attributed to Stephen Jodelle, on Noſtradamus's character, is well known.

Noſtra damus, cum falſa damus, nam fallere noſtrum eſt:
Et cum falſa damus, nil niſi Noſtra damus.

NOSTRE (Andrew le), comptroller of the buildings of the French king, and deſigner of his gardens, diſtinguiſhed himſelf by carrying the art of laying out gardens to great perfection. He was born at Paris in 1631; and was near 40 years of age when M. Fouquet ſuperintendant of the finances gave him

an opportunity of becoming known by the fine gardens of Vaux-le-Vicomte. He was afterwards employed by Lewis XIV. at Verfailles, Trianon, St Germains, &c. and difcovered an admirable tafte in all his works. In 1678 he went to Rome, with the permiffion of the French king, to improve his fkill; but he found nothing there comparable to what he himfelf had done. Pope Innocent XI. refolved to fee Le Noftre, and gave him a pretty long audience; at the conclufion of which Le Noftre faid, "I have feen the two greateft men in the world; your holinefs, and the king my mafter." There is a great difference, anfwered the pope: "The king is a great victorious prince; and I am a poor prieft, the fervant of the fervants of God." Le Noftre, charmed with this anfwer, and forgetting who he was with, clapped the pope on the fhoulder, faying, "Reverend father, you look extremely well, and will live to bury all the facred college." The pope laughed at his prediction. Le Noftre, charmed more and more at the goodnefs of the fovereign pontiff, and the fingular efteem he fhewed for the king, threw his arms about the pope's neck and kiffed him. It was his cuftom to behave in the fame manner to all who fpoke in praife of Lewis XIV. and he even embraced the king himfelf whenever that prince returned from the country. Le Noftre had alfo a talent for painting. He preferved his good fenfe and vivacity of mind to the end of his life; and died at Paris in 1700, aged 87.

NOTARY, (NOTARIUS), fignifies a perfon, ufually fome fcrivener, who takes notes, or frames fhort draughts, of contracts, obligations, charter-parties, or other writings. At prefent we call him a *notary-public*, who publicly attefts deeds, or writings, in order to make them authentic in another nation: but he is principally employed in bufinefs concerning merchants; as making protefts of bills of exchange, &c. And noting a bill, is where he goes to take notice of a merchant's refufal to accept or pay the fame.

NOTATION, in arithmetic and algebra, the method of expreffing numbers or quantities by figns or characters appropriated for that purpofe. See ARITHMETIC and ALGEBRA.

NOTES, in mufic, characters which mark the founds, *i. e.* the elevations and fallings of the voice, and the fwiftnefs and flownefs of its motions.

NOTE is likewife ufed for a mark made in a book or writing, where there occurs fomething remarkable and worthy of particular notice: as alfo for an obfervation or explication of fome paffage in an author added in the margin, at the bottom of the page, or elfewhere; in which fenfe it ftands contradiftinguifhed to *text*.

NOTE, is alfo a minute, or fhort writing, containing fome article of bufinefs; in which fenfe we fay, promiffory note, note of hand, bank-note, &c.

NOTHUS, fignifies *fpurious*, or *baftard;* whence it is figuratively applied by phyficians to fuch difeafes as, though in a refpect of a fimilitude of fymptoms, &c. they have the fame denomination as fome others, yet are of a different origin, feat, or the like, from the fame.

NOTION, in logic, an idea or reprefentation of any thing in the mind. See LOGIC and METAPHYSICS.

NOTITIA, in literary hiftory, a book that gives an account of a particular country, city, or other place: fuch is the *Notitia Imperii Romani*, *Notitia Romæ Antiquæ*, &c.

NOTO, an ancient, large, and handfome town of Sicily, and capital of the Val-di-Noto. It was entirely ruined by an earthquake in 1693; but the inhabitants built another town at fome diftance from it, which they call *Noto Nuovo*. E. Long. 14. 0. N. Lat. 36. 50.

NOTO (*Val-di*), one of the three valleys or provinces into which Sicily is divided; and it lies between the fea, Val-di-Demona, and Val-di-Mazara. Noto is the capital town.

NOTONECTA, the BOAT-FLY; a genus of infects belonging to the order of hemiptera. It generally inhabits the water, and alway fwims on its back, and is very fwift in its motions. Its belly, which it fhews while in the water, is of a yellowifh white; its legs are long; when taken out of the water, it hops. It is indeed a very beautiful and very nimble little creature; and is common in the ponds of water in Hyde-park, and in feveral other places about London. It has four wings, fix legs, and no antennæ; it is eight inches long, three broad, and two and a half thick. The body is black, and of a very particular form, being flattifh at the belly, and rifing to a ridge on the middle of the back; fo that when it fwims, which is almoft always on the back, its body refmbles a boat in figure.

The belly is jointed, ftriated, and hairy; and has a large opening at the tail, out of which, when hurt, it thrufts forth fomething refembling a fting. The head and fhoulders are large, hard, and yellow, without any fpots; the eyes are large and red, and of a fomewhat triangular form. The nofe is a long, green, hollow probofcis, terminating in a hard and fharp brown point; this, in its natural pofture, is kept under the belly, and reaches to the middle pair of legs. The outer pair of wings are of a pale flefh-colour, with fpots of a dead white; thefe are long, narrow, and fomewhat tranfparent: they terminate in a roundifh point, and perfectly cover the whole body. The triangular piece which ftands between the top of the wings is hard, and perfectly black; the inner wings are broader and fhorter than the outer ones; they are thin and perfectly tranfparent, and are of a pale pearl colour. The legs are green and hairy; the foremoft pair are fhorteft; the middle ones longer than thefe; but the hinder pair are greatly longer than all the reft, fo that they ferve as oars, and are tufted with hair at the end to that purpofe. This creature moftly lives in the water, where it preys on fmall infects, killing them and fucking their juices with its probofcis, in the manner of the water-fcorpion and many other aquatic infects; and it feizes its prey violently, and darts with incredible fwiftnefs to a confiderable diftance after it.

Though it generally lives in the water, it fometimes, however, crawls out in good weather; and drying its wings by expanding them in the fun, takes flight, and becomes an inhabitant of the air, not to be known for the fame creature, unlefs to thofe who had accurately obferved it before; when tired of flying, or in danger of an enemy, it immediately plunges into the water. If taken into the hand, it ftings, and

Notteberg, Nottingharnshire. gives an intolerable pain, but this goes off in a very few minutes. This is the ſpecies moſt frequently met with; but it is not the only *notonecta* we have, three or four other kinds, different in ſize and colour, being found not unfrequently in large waters.

NOTTEBURG, a town of Ruſſia, in the province of Ingria, ſeated on an iſland in the lake Ladoga, at the place where the river Nieva proceeds from this lake. It is ſtrong, has a good citadel, and was capital of the province before Peterſburg was built. E. Long. 31. 40. N. Lat. 60. 0.

NOTTINGHAMSHIRE, a county of England, bounded on the eaſt by Lincolnſhire, on the ſouth-eaſt and ſouth by Leiceſterſhire, on the weſt by Derbyſhire, and on the north and north-weſt by Yorkſhire. It extends in length 43 miles, 24 in breadth, and 110 miles in compaſs; containing 560,000 acres, 8 hundreds, 9 market-town, 168 pariſhes, 450 villages, about 17500 houſes, and 95000 inhabitants. No county in England enjoys a pleaſanter and healthier air. As for the ſoil, it differs widely in different parts of the county. Towards the weſt, where lies the foreſt of Sherwood, it is ſandy; and therefore that part of the county is called by the inhabitants, the *Sand:* but the ſouth and eaſt parts, watered by the Trent and the rivulets that fall into it, are clayey; and for that reaſon are called by the inhabitants, the *Clay*. The latter is fruitful both in corn and paſture; but the former produces little beſides wood, coal, and ſome lead. The county has a variety of commodities and manufactures, as wool, leather, tallow, butter, cheeſe, coal, marle, cattle, malt, liquorice, ſtockings, glaſs, earthen-wares, and ſtrong ale. The principal rivers are the Trent and Idle. The Trent, whoſe name is ſuppoſed to be derived from the French or Latin word ſignifying *thirty*, either becauſe it receives thirty ſmaller rivers, or has thirty different ſorts of fiſh in it, is inferior to no river in England, but the Severn, Thames, and Humber. It enters the county on the ſouth-weſt, and paſſes through it to the north-eaſt, where it enters Lincolnſhire, and after a long courſe falls at laſt into the Humber. The Idle riſes in Sherwood-foreſt; and after traverſing the northern part of the county, falls into the Trent upon the borders of Yorkſhire and Lincolnſhire.

The ſpacious foreſt of Sherwood lies in the weſt part of the county, and indeed takes up the greateſt part of it. It was formerly ſo thick, that it was hardly paſſable; but now it is much thinner. It feeds an infinite number of deer and ſtags; and has ſome towns in it, of which Mansfield is the chief. It abounds in coal, and a road lies through it for thirty miles together. Since the reign of king Edward I. the nobility and gentry have had grants of it. It is governed by a great number of officers under the earl of Cheſterfield, chief foreſter; whoſe anceſtor, Sir John Stanhope, had a grant of it, with liberty to deſtroy and kill at pleaſure, reſerving only an hundred deer in the whole walk. The principal town is

NOTTINGHAM, which gives name to the county. It is a handſome town, and a county of itſelf by charter. The name is derived from the Saxon word *Snottengham*, which ſignifies caves, from the caves and apartments anciently dug in the rocks on which the town ſtands. Theſe, being ſoft, eaſily yield to the ſpade and pickaxe; whence the townſmen have excellent cellars for the vaſt quantities of malt liquors made here, and ſent, as well as their malt, to moſt parts of England. The ſituation of the town is very pleaſant, having meadows on one hand, and hills of a gentle, eaſy aſcent, on the other. It is well ſupplied with fuel, both wood and coal, from the foreſt; and with fiſh by the Trent, which runs about a mile to the ſouth of it, and has been made navigable for barges: ſo that they receive by it not only great quantities of cheeſe from Warwickſhire and Staffordſhire; but all their heavy goods from the Humber, and even from Hull. It is of great antiquity; and had anciently a very ſtrong caſtle, where is now a fine ſeat belonging to the duke of Newcaſtle. It is noted for its horſe-races on a fine courſe on the north ſide of the town. The corporation is governed by a mayor, recorder, ſix aldermen, two coroners, two ſheriffs, two chamberlains, and twenty-four common-council men, eighteen of the ſenior-council, and ſix of the junior, a bell-bearer, and two pinders, one for the fields, and the other for the meadows. The town being within the juriſdiction of the foreſt, the former of theſe pindars is town-woodward, and attends the foreſt courts. It has three neat churches, the chief of which is St Mary's; and an alm-houſe, endowed with 100 l. a-year, for twelve poor people; with a noble town-houſe, ſurrounded with piazzas. A conſiderable trade is carried on in glaſs and earthen-wares, and frame-ſtockings, beſides the malt, and malt-liquors, mentioned above. Marſhal Tallard, when a priſoner in England, was confined to this town and county. In the duke of Newcaſtle's park there is a ledge of rocks hewn into a church, houſes, chambers, dove-houſes, &c. The altar of the church is natural rock, and between that and the caſtle there is an hermitage of the like workmanſhip. Upon the ſide of a hill there is a very extraordinary ſort of a houſe, where you enter at the garret, and aſcend to the cellar, which is at the top of the houſe. Here is a noted hoſpital founded by John Plumtree, Eſq; in the reign of Richard II. for thirteen poor old widows. There are four handſome bridges over the Trent and Lind. To keep theſe in repair, and other uſes, the corporation has good eſtates. This town and Winchelſea both give title of earl to the noble family of Finch. Here David, king of Scots, when a priſoner in England, reſided; and under-ground in a vault, called *Mortimer's hole*, becauſe Roger Mortimer, earl of March, is ſaid to have abſconded in it, when he was taken and hanged by order of Edward III.

Nottingham. Nova.

NOVA-SCOTIA. See *Nova*-SCOTIA.

NOVA *Zembla*. See *Nova* ZEMBLA.

NOVALLE, a ſmall, rich, and populous town of Italy, between Padus and Treviſo. E. Long. 12. 5. N. Lat. 45. 35.

NOVARA, an ancient, well built, and ſtrong town of Italy, in the duchy of Milan, and capital of the Novareſe, with a biſhop's ſee; ſeated upon an eminence. E. Long. 8. 35. N. Lat. 45. 25.

NOVATIANS, a Chriſtian ſect which ſprung up in the third century, ſo called from Novatian a prieſt of Rome, or Novatus. See NOVATUS.

NOVATION, or INNOVATION, in the civil law, denotes the change of one kind of obligation for another;

ther; as when a promife is accepted inftead of a written obligation.

NOVATUS, a prieft of Carthage, in the third century, who, to avoid being punifhed for a crime, jonied with the deacon, named *Feliciffimus*, againft St Cyprian. He went to Rome in 251; and there found Novatian, a prieft who had acquired great reputation by his eloquence; but who murmured at his not being raifed to the fee of Rome in preference to pope Cornelius. Novatus contracted a friendfhip with him; and afterwards, it is faid, getting three ignorant bifhops, made them drunk, and then obliged them to ordain Novatian bifhop of Rome. This irregular ordination produced a very great fchifm; both Novatus and Novatian maintained, that the church had not the power to receive thofe to communion who were fallen into idolatry. There are attributed to Novatian, the treatife on the Trinity, and the book on Jewifh meats, which are among Tertullian's works; and it was he, and not Novatus, who gave his name to the fect called *Novatians*.

NOVEL, in matters of literature, a fictitious hiftory of a feries of entertaining events in common life, wherein the rules of probability are, or ought to be, ftrictly preferved.

Novel, in the civil law, a term ufed for the conftitutions of feveral emperors, more particularly thofe of Juftinian. They were called *novels*, either from their producing a great alteration in the face of the ancient law, or becaufe they were made on new cafes, and after the revifal of the ancient code.

NOVELTY, or Newness. Of all the circumftances that raife emotions, not excepting beauty, nor even greatnefs, fays Lord Kames †, novelty hath the moft powerful influence. A new object produceth inftantaneoufly an emotion termed *wonder*, which totally occupies the mind, and for a time excludes all other objects. Converfation among the vulgar never is more interefting than when it turns upon ftrange objects and extraordinary events. Men tear themfelves from their native country in fearch of things rare and new; and novelty converts into a pleafure, the fatigues and even perils of travelling. To what caufe fhall we afcribe thefe fingular appearances? To curiofity undoubtedly; a principle implanted in human nature for a purpofe extremely beneficial, that of acquiring knowledge; and the emotion of wonder raifed by new and ftrange objects, inflames our curiofity to know more of fuch objects. This emotion is different from *admiration:* novelty, wherever found, whether in a quality or action, is the caufe of wonder; admiration is directed to the perfon who performs any thing wonderful.

† *Elem. of Criticifm.*

During infancy, every new object is probably the occafion of wonder, in fome degree; becaufe, during infancy, every object at firft fight is ftrange as well as new: but as objects are rendered familiar by cuftom, we ceafe by degrees to wonder at new appearances, if they have any refemblance to what we are acquainted with; for a thing muft be fingular as well as new, to raife our wonder. To fave multiplying words, we would be underftood to comprehend both circumftances when we hereafter talk of novelty.

In an ordinary train of perceptions where one thing introduces another, not a fingle object makes its appearance unexpectedly †: the mind thus prepared for the reception of its objects, admits them one after another without perturbation. But when a thing breaks in unexpectedly, and without the preparation of any connection, it raifes an emotion, known by the name of *furprife*. That emotion may be produced by the moft familiar object, as when one unexpectedly meets a friend who was reported to be dead; or a man in high life, lately a beggar. On the other hand, a new object, however ftrange, will not produce the emotion, if the fpectator be prepared for the fight: an elephant in India will not furprife a traveller who goes to fee one; and yet its novelty will raife his wonder: an Indian in Britain would be much furprifed to ftumble upon an elephant feeding at large in the open fields; but the creature itfelf, to which he was accuftomed, would not raife his wonder.

† See the article Perceptions.

Surprife thus in feveral refpects differs from wonder: unexpectednefs is the caufe of the former emotion; novelty is the caufe of the latter. Nor differ they lefs in their nature and circumftances, as will be explained by and by. With relation to one circumftance they perfectly agree; which is, the fhortnefs of their duration: the inftantaneous production of thefe emotions in perfection, may contribute to that effect, in conformity to a general law, That things foon decay which foon come to perfection: the violence of the emotions may alfo contribute; for an ardent emotion, which is not fufceptible of increafe, cannot have a long courfe. But their fhort duration is occafioned chiefly by that of their caufes: we are foon reconciled to an object, however unexpected; and novelty foon degenerates into familiarity.

Whether thefe emotions be pleafant or painful, is not a clear point. It may appear ftrange, that our own feelings and their capital qualities, fhould afford any matter for a doubt: but when we are engroffed by any emotion, there is no place for fpeculation; and when fufficiently calm for fpeculation, it is not eafy to recal the emotion with accuracy. New objects are fometimes terrible, fometimes delightful: the terror which a tyger infpires is greateft at firft, and wears off gradually by familiarity: on the other hand, even women will acknowledge that it is novelty which pleafes the moft in a new fafhion. It would be rafh however to conclude, that wonder is itfelf neither pleafant nor painful, but that it affumes either quality according to circumftances. An object, it is true, that hath a threatening appearance, adds to our terror by its novelty: but from that experiment it doth not follow, that novelty is in itfelf difagreeable; for it is perfectly confiftent, that we be delighted with an object in one view, and terrified with it in another. A river in flood fwelling over its banks, is a grand and delightful object; and yet it may produce no fmall degree of fear when we attempt to crofs it: courage and magnanimity are agreeable; and yet, when we view thefe qualities in an enemy, they ferve to increafe our terror. In the fame manner, novelty may produce two effects clearly diftinguifhable from each other: it may, directly and in itfelf, be agreeable; and it may have an oppofite effect indirectly, which is, to infpire terror; for when a new object appears in any degree danger-

ous,

Novelty.

ous, our ignorance of its powers and faculties affords ample fcope for the imagination to drefs it in the moft frightful colours. The firft fight of a lion, for example, may at the fame inftant produce two oppofite feelings, the pleafant emotion of wonder, and the painful paffion of terror: the novelty of the object produces the former directly, and contributes to the latter indirectly. Thus when the fubject is analifed, we find, that the power which novelty hath indirectly to inflame terror, is perfectly confiftent with its being in every circumftance agreeable. The matter may be put in the cleareft light, by adding the following circumftances. If a lion be firft feen from a place of fafety, the fpectacle is altogether agreeable without the leaft mixture of terror. If, again, the firft fight puts us within reach of that dangerous animal, our terror may be fo great as quite to exclude any fenfe of novelty. But this fact proves not that wonder is painful: it proves only, that wonder may be excluded by a more powerful paffion. Every man may be made certain from his own experience, that wonder raifed by a new object that is inoffenfive, is always pleafant; and with refpect to offenfive objects, it appears, from the foregoing deduction, that the fame muft hold as long as the fpectator can attend to the novelty.

Whether furprife be in itfelf pleafant and painful, is a queftion not lefs intricate than the former. It is certain that furprife inflames our joy when unexpectedly we meet with an old friend; and not lefs our terror when we ftumble upon any thing noxious. To clear that queftion, the firft thing to be remarked is, that in fome inftances an unexpected object overpowers the mind, fo as to produce a momentary ftupefaction: where the object is dangerous, or appears fo, the fudden alarm it gives, without preparation, is apt totally to unhinge the mind, and for a moment to fufpend all its faculties, even thought itfelf; in which ftate a man is quite helplefs; and if he move at all, is as like to run upon the danger as from it. Surprife carried to fuch a height, cannot be either pleafant or painful; becaufe the mind, during fuch momentary ftupefaction, is in a good meafure, if not totally, infenfible.

If we then inquire for the character of this emotion, it muft be where the unexpected object or event produceth lefs violent effects. And while the mind remains fenfible of pleafure and pain, is it not natural to fuppofe, that furprife, like wonder, fhould have an invariable character? It would appear, however, that furprife has no invariable character, but affumes that of the object which raifes it. Wonder being an emotion invariably raifed by novelty, and being diftinguifhable from all other emotions, ought naturally to poffefs one conftant character. The unexpected appearance of an object, feems not equally intitled to produce an emotion diftinguifhable from the emotion, pleafant or painful, that is produced by the object in its ordinary appearance: the effect it ought naturally to have, is only to fwell that emotion, by making it more pleafant or more painful than it commonly is. And that conjecture is confirmed by experience, as well as by language which is built upon experience: when a man meets a friend unexpectedly, he is faid to be agreeably furprifed; and when he meets an enemy unexpectedly, he is faid to be difagreeably furprifed. It appears, then, that the fole effect of furprife is to fwell the emotion raifed by the object. And that effect can be clearly explained: a tide of connected perceptions glide gently into the mind, and produce no perturbation; but an object breaking in unexpectedly, founds an alarm, roufes the mind out of its calm ftate, and directs its whole attention to the object, which, if agreeable, becomes doubly fo. Several circumftances concur to produce that effect: on the one hand, the agitation of the mind and its keen attention, prepare it in the moft effectual manner for receiving a deep impreffion: on the other hand, the object, by its fudden and unforefeen appearance, makes an impreffion, not gradually as expected objects do, but as at one ftroke with its whole force. The circumftances are precifely fimilar where the object is in itfelf difagreeable (A).

The pleafure of novelty is eafily diftinguifhed from that of variety: to produce the latter, a plurality of objects is neceffary; the former arifes from a circumftance found in a fingle object. Again, where objects, whether coexiftent or in fucceffion, are fufficiently diverfified, the pleafure of variety is complete, though every fingle object of the train be familiar; but the pleafure of novelty, directly oppofite to familiarity, requires no diverfification.

There are different degrees of novelty, and its effects are in proportion. The loweft degree is found in objects furveyed a fecond time after a long interval; and that in this cafe an object takes on fome appear-

(A) What the Marefchal Saxe terms *le cœur humain*, is no other than fear occafioned by furprife. It is owing to that caufe that an ambufh is generally fo deftructive: intelligence of it beforehand renders it perfectly harmlefs. The Marefchal gives from Cæfar's Commentaries two examples of what he calls *le cœur humain*. At the fiege of Amiens by the Gauls, Cæfar came up with his army, which did not exceed 7000 men; and began to intrench himfelf in fuch hurry, that the barbarians, judging him to be afraid, attacked his intrenchments with great fpirit. During the time they were filling up the ditch, he iffued out with his cohorts, and by attacking them unexpectedly ftruck a panic that made them fly with precipitation, not a fingle man offering to make a ftand. At the fiege of Alefia, the Gauls infinitely fuperior in number attacked the Roman lines of circumvallation, in order to raife the fiege. Cæfar ordered a body of his men to march out filently, and to attack them on the one flank, while he with another body did the fame on the other flank. The furprife of being attacked when they expected a defence only, put the Gauls into diforder, and gave an eafy victory to Cæfar.

A third may be added not lefs memorable. In the year 846, an obftinate battle was fought between Xamire king of Leon, and Abdoulrahman the Moorifh king of Spain. After a very long conflict, the night only prevented the Arabians from obtaining a complete victory. The king of Leon, taking advantage of the darknefs, retreated to a neighbouring hill, leaving the Arabians mafters of the field of battle. Next morning, perceiving that he could not maintain his place for want of provifions, nor be able to draw off his men in the face of a victorious army, he ranged his men in order of battle, and, without lofing a moment, marched to attack the enemy, refolving to conquer or die. The Arabians, aftonifhed to be attacked by thofe who were conquered the night before, loft all heart: fear fucceeded to aftonifhment, the panic was univerfal, and they all turned their backs without almoft drawing a fword.

ance of novelty, is certain from experience: a large building of many parts variouſly adorned, or an extenſive field embelliſhed with trees, lakes, temples, ſtatues, and other ornaments, will appear new oftener than once: the memory of an object ſo complex is ſoon loſt, of its parts at leaſt, or of their arrangement. But experience teaches, that, even without any decay of remembrance, abſence alone will give an air of novelty to a once familiar object; which is not ſurpriſing, becauſe familiarity wears off gradually by abſence: thus a perſon with whom we have been intimate, returning after a long interval, appears like a new acquaintance. And diſtance of place contributes to this appearance, not leſs than diſtance of time: a friend, for example, after a ſhort abſence in a remote country, has the ſame air of novelty as if he had returned after a longer interval from a place nearer home: the mind forms a connection between him and the remote country, and beſtows upon him the ſingularity of the objects he has ſeen. For the ſame reaſon, when two things equally new and ſingular are preſented, the ſpectator balances between them; but when told that one of them is the product of a diſtant quarter of the world, he no longer heſitates, but clings to it as the more ſingular: hence the preference given to foreign luxuries, and to foreign curioſities, which appear rare in proportion to their original diſtance.

The next degree of novelty, mounting upward, is found in objects of which we have ſome information at ſecond hand; for deſcription, though it contribute to familiarity, cannot altogether remove the appearance of novelty when the object itſelf is preſented: the firſt ſight of a lion occaſions ſome wonder, after a thorough acquaintance with the correcteſt pictures and ſtatues of that animal.

A new object that bears ſome diſtant reſemblance to a known ſpecies, is an inſtance of a third degree of novelty: a ſtrong reſemblance among individuals of the ſame ſpecies, prevents almoſt entirely the effect of novelty, unleſs diſtance of place or ſome other circumſtance concur; but where the reſemblance is faint, ſome degree of wonder is felt, and the emotion riſes in proportion to the faintneſs of the reſemblance.

The higheſt degree of wonder ariſeth from unknown objects that have no analogy to any ſpecies we are acquainted with. Shakeſpeare in a ſimile introduces that ſpecies of novelty:

> As glorious to the ſight
> As is a winged meſſenger from heaven
> Unto the white up-turned wond'ring eye
> Of mortals, that fall back to gaze on him
> When he beſtrides the lazy-pacing clouds
> And ſails upon the boſom of the air.
>
> *Romeo and Juliet.*

One example of that ſpecies of novelty deſerves peculiar attention; and that is, when an object altogether new is ſeen by one perſon only, and but once. Theſe circumſtances heighten remarkably the emotion: the ſingularity of the ſpectator concurs with the ſingularity of the object, to inflame wonder to its higheſt pitch.

In explaining the effects of novelty, the place a being occupies in the ſcale of exiſtence, is a circumſtance that muſt not be omitted. Novelty in the individuals of a low claſs is perceived with indifference, or with a very ſlight emotion: thus a pebble, however ſingular in its appearance, ſcarce moves our wonder. The emotion riſes with the rank of the object; and, other circumſtances being equal, is ſtrongeſt in the higheſt order of exiſtence; a ſtrange inſect affects us more than a ſtrange vegetable; and a ſtrange quadruped more than a ſtrange inſect.

However natural novelty may be, it is a matter of experience, that thoſe who reliſh it the moſt are careful to conceal its influence. Love of novelty, it is true, prevails in children, in idlers, and in men of ſhallow underſtanding: and yet, after all, why ſhould one be aſhamed of indulging a natural propenſity? A diſtinction will afford a ſatisfactory anſwer. No man is aſhamed of curioſity when it is indulged to acquire knowledge. But to prefer any thing merely becauſe it is new, ſhows a mean taſte which one ought to be aſhamed of: vanity is commonly at the bottom, which leads thoſe who are deficient in taſte to prefer things odd, rare, or ſingular, in order to diſtinguiſh themſelves from others. And in fact, that appetite, as abovementioned, reigns chiefly among perſons of a mean taſte, who are ignorant of refined and elegant pleaſures.

One final cauſe of wonder, hinted above, is, that this emotion is intended to ſtimulate our curioſity. Another, ſomewhat different, is, to prepare the mind for receiving deep impreſſions of new objects. An acquaintance with the various things that may affect us, and with their properties, is eſſential to our well-being: nor will a ſlight or ſuperficial acquaintance be ſufficient; they ought to be ſo deeply engraved on the mind, as to be ready for uſe upon every occaſion. Now, in order to a deep impreſſion, it is wiſely contrived, that things ſhould be introduced to our acquaintance with a certain pomp and ſolemnity productive of a vivid emotion. When the impreſſion is once fairly made, the emotion of novelty being no longer neceſſary, vaniſheth almoſt inſtantaneouſly; never to return, unleſs where the impreſſion happens to be obliterated by length of time or other means, in which caſe the ſecond introduction hath nearly the ſame ſolemnity with the firſt.

Deſigning wiſdom is no where more eligible than in this part of the human frame. If new objects did not affect us in a very peculiar manner, their impreſſions would be ſo ſlight as ſcarce to be of any uſe in life: on the other hand, did objects continue to affect us as deeply as at firſt, the mind would be totally engroſſed with them, and have no room left either for action or reflection.

The final cauſe of ſurpriſe is ſtill more evident than of novelty. Self-love makes us vigilantly attentive to ſelf-preſervation; but ſelf-love, which operates by means of reaſon and reflection, and impels not the mind to any particular object or from it, is a principle too cool for a ſudden emergency; an object breaking in unexpectedly, affords no time for deliberation; and in that caſe, the agitation of ſurpriſe comes in ſeaſonably to rouſe ſelf-love into action: ſurpriſe gives the alarm; and if there be any appearance of danger, our whole force is inſtantly ſummoned to ſhun or to prevent it.

NOVELLARA, a handſome town of Italy, and capital of a ſmall diſtrict of the ſame name, with a handſome caſtle, where their ſovereign reſides. E. Lon. 10.

Novemviri || Noviodunum.

10. 37. N. Lat. 45. 50.

NOVEMVIRI, nine magiftrates of Athens, whofe government lafted but for one year. The firft of whom was called *archon*, or prince; the fecond *bafilius*, or king; the third *polemarchus*, or general of the army: the other fix were called *thefmothetæ*, or lawgivers. They took an oath to obferve the laws; and in cafe of failure, obliged themfelves to beftow upon the commonwealth a ftatue of gold as big as themfelves. Thofe who difcharged their office with honour, were received into the number of the fenators of Areopagus.

NOVI, a town of Italy, in the territory of Genoa, on the confines of the Milanefe. It was taken by the Piedmontefe in 1746. E. Long. 8. 48. N. Lat. 44. 45.

Novi-*Bazar*, a confiderable town of Turkey in Europe, and in Servia, near the river Orefco. E. Long. 20. 24. N. Lat. 43. 25.

NOVIGRAD, a fmall but ftrong town of Upper Hungary, capital of a county of the fame name, with a good caftle, feated on a mountain near the Danube. E. Long. 18. 10. N. Lat. 47. 50.

Novigrad, a fmall but ftrong town of Dalmatia, with a caftle, and fubject to the Turks; feated on a lake of the fame name, near the gulph of Venice. E. Long. 16. 45. N. Lat. 44. 30.

Novigrad, a very ftrong place of Servia, fubject to the Turks; feated near the Danube. E. Long. 26. 5. N. Lat. 45. 5.

NOVICE, a perfon not yet fkilled or experienced in an art or profeffion.

In the ancient Roman militia, *novicii*, or *novitii*, were the young raw foldiers, diftinguifhed by this appellation from the veterans.

In the ancient orders of knighthood, there were novices, or clerks in arms, who went through a kind of apprenticefhip ere they were admitted knights. See Knight.

Novice is more particularly ufed in monafteries for a religious yet in his, or her, year of probation, and who has not made the vows.

In fome convents, the fub-prior has the direction of the novices. In nunneries, the novices wear a white veil; the reft a black one.

NOVICIATE, a year of probation appointed for the trial of religious, whether or no they have a vocation, and the neceffary qualities for living up to the rule; the obfervation whereof they are to bind themfelves to by vow. The noviciate lafts a year at leaft; in fome houfes more. It is efteemed the bed of the civil death of a novice, who expires to the world by profeffion.

NOVIODUNUM (Cæfar), a town of the Ædui, commodioufly feated on the Liguris: the *Nivernum* of Antonine. Now *Nevers* in the Orleanois, on the Loire.—A fecond *Noviodunum* of the Aulerci Diablintes, in Gallia Celtica, (Antonine); called *Noviodunum*, (Ptolemy), and *Noningentum Rotrudum* by the moderns: *Nogente le Rotrou*, capital of the duchy of Perche.—A third, of the Bituriges. (Cæfar): Now *Nueve fur Baranion*; a village 15 miles to the north of Bourges, towards Orleans.—A fourth, of Mœfia Inferior, (Ptolemy), fituate on the Ifter: now *Nivorz*, in Beffarabia.—A fifth, of Pannonia Superior, (Antonine); now *Gurkfeld* in Carinthia.—A fixth *Noviodunum Sueffionum*, the fame with *Augufta Sueffionum*. —A feventh, *Noviodunum* of the Veromandui in Gallia Belgica, (Cæfar): now *Noyon* in the Ifle of France, on the borders of Picardy.

Novogorod || Nubecula.

NOVOGOROD welicki, or *Great Novogorod*, a rich and very large town of the Ruffian empire, and capital of a duchy of the fame name, with an archbifhop's fee, and a caftle where the archbifhop and the waiwode refide. It is commonly called the *grand magazine*, becaufe hither they bring their rich merchandifes that come from the Levant. It contains 180 churches and monafteries, and carries on a great trade in Ruffia leather. It is feated on the river Wolcoff, near the lake Honen. E. Long. 33. 40. N. Lat. 58. 23.

Novogorod *Welicki*, a province of Mofcow, bounded on the north by Ingria; on the eaft by part of the duchy of Belozero, and that of Tuera, which alfo bounds it on the fouth, with the province of Rzeva; and on the weft by Plefcow. It is full of lakes and forefts; however, there are fome places which produce corn, flax, hemp, honey, and wax.

Novogorod *Serpfkoi*, a ftrong town of the Ruffian empire, and capital of a province of Siberia of the fame name, feated on the river Dubica, in E. Long. 33. 20. N. Lat 52. 30.

NOVOGORODECK, a town of Lithuania, and capital of a palatinate of the fame name. It is a large town, and fituated in a vaft plain, in E. Long. 25. 30. N. Lat. 53. 45.

NOURISHMENT. See Nutrition.

Nourishment *of Vegetables*. See Agriculture, Part I. Sect. 1. and 2. and Plants; alfo the article Composts.

NOWED, in heraldry, fignifies "knotted," from the Latin *nodatus*; being applied to the tails of fuch creatures as are very long, and fometimes reprefented in coat-armour as tied up in a knot.

NUAYHAS, the Ague-tree; a name given by the Indians to a fort of Bamboo-cane, the leaves of which falling into the water, are faid to impregnate it with fuch virtue, that the bathing in it afterwards will cure the ague. They ufe alfo a decoction of the leaves to diffolve coagulated blood, giving it internally, and at the fame time rubbing the bruifed part externally with it. It is faid that this plant bears its flowers only once in its life; that it lives 60 years before thefe make their appearance; but that when they begin to fhew themfelves, it withers away in about a month afterwards; that is, as foon as it has ripened the feed. There feems to be fomething of fiction in the account of many other particulars relating to this tree in the *Hortus Malabaricus*; but it feems certain, that the length of the ftalks, or trunk, muft be very great: for, in the gallery of Leyden, there is preferved a cane of it 28 feet long; and another not much fhorter in the Afhmolean mufeum at Oxford, and which is more than eight inches in diameter: yet both thefe appear to be only parts of the whole trunk, they being nearly as large at one end as at the other.

NUBECULA, little cloud, in medicine, a term fometimes ufed for difeafe in the eye, wherein objects appear as through a cloud or mift.

The

The nubecula feems to arife from certain grofs particles detained in the pores of the cornea, or fwimming in the aqueous humour, and thus intercepting the rays of light.

Nubecula, or *Nubes*, is alfo ufed for what we otherwife call *albugo*. See Albugo.

Nubecula is alfo ufed for a matter in form of a cloud, fufpended in the middle of the urine.

NUBIA, a country of Africa, bounded on the north by Egypt, on the fouth by Abyffinia, on the eaft by the coaft of Abefh or Abex, and on the weft by Zaara and Nigritia. It is faid to be 400 leagues in length, and 200 in breadth, and to be watered by a river which falls into the Nile; but of thefe dimenfions we have little certainty, and nothing can be depended upon concerning the nature of the country or its inhabitants.

NUCLEUS, in general, denotes the kernel of a nut, or even any feed inclofed within a hufk. The term *nucleus* is alfo ufed for the body of a comet, otherwife called its *head*.

NUDITIES, in painting and fculpture, thofe parts of an human figure which are not covered with any drapery; or thofe parts where the carnation appears.

NULLITY, in law, fignifies any thing that is null or void: thus there is a nullity of marriage, where perfons marry within the degrees, or where infants marry without confent of their parents or guardians.

NUMANTIA, a very noble city, the ornament of the Hither Spain, (Florus); as appears from the Numantine war; and though deftroyed by the Romans under Scipio Æmilianus, it was afterwards no doubt reftored, becaufe mentioned not only by Ptolemy, but alfo by Antonine, who determines its fituation between Uxama and Turiafo; and Strabo fays, the Durius run by it, while ftill recent and near its fource. With 4000 men it held out a fiege of 14 years, againft 40,000 Romans. And all this it did, like another Sparta, without walls and without turrets; but this is doubtfully mentioned by authors.—*Numantini*, the people; who, after a tedious and clofe fiege, and after ftruggling long with famine, at length deftroyed themfelves and their city by fire.

NUMBER, an affemblage of feveral units, or things of the fame kind. See Arithmetic; and Metaphysics, n° 62—65.

Number, fays Malcolm, is either abftract or applicate: Abftract, when referred to things in general, without attending to their particular properties; and applicate, when confidered as the number of a particular fort of things, as yards, trees, or the like.

When particular things are mentioned, there is always fomething more confidered than barely their numbers; fo that what is true of numbers in the abftract, or when nothing but the number of things is confidered, will not be true when the queftion is limited to particular things: for inftance, the number two is lefs than three; yet two yards is a greater quantity than three inches: and the reafon is, becaufe regard muft be had to their different natures as well as number, whenever things of a different fpecies are confidered; for though we can compare the number of fuch things abftractedly, yet we cannot compare them in any applicate fenfe. And this difference is neceffary to be confidered, becaufe upon it the true fenfe, and the poffibility or impoffibility, of fome queftions depend.

Number is unlimited in refpect of increafe; becaufe we can never conceive a number fo great, but ftill there is a greater. However, in refpect of decreafe, it is limited; unity being the firft and leaft number, below which therefore it cannot defcend.

Kinds and Diftinctions of Numbers. Mathematicians, confidering number under a great many relations, have eftablifhed the following diftinctions.

Broken numbers are the fame with fractions.

Cardinal numbers are thofe which exprefs the quantity of units, as 1, 2, 3, 4, *&c.* whereas ordinal numbers are thofe which exprefs order, as 1ft, 2d, 3d, *&c.*

Compound number, one divifible by fome other number befides unity; as 12, which is divifible by 2, 3, 4, and 6. Numbers, as 12 and 15, which have fome common meafure befides unity, are faid to be compound numbers among themfelves.

Cubic number is the product of a fquare number by its root: fuch is 27, as being the product of the fquare number 9, by its root 3. All cubic numbers, whofe root is lefs than 6, being divided by 6, the remainder is the root itfelf: thus $27 \div 6$ leaves the remainder 3, its root; 215, the cube of 6, being divided by 6, leaves no remainder; 343, the cube of 7, leaves a remainder 1, which, added to 6, is the cube root; and 512, the cube of 8, divided by 6, leaves a remainder 2, which, added to 6, is the cube root. Hence the remainders of the divifions of the cubes above 216, divided by 6, being added to 6, always gives the root of the cube fo divided, till that remainder be 5, and confequently 11, the cube-root of the number divided. But the cubic numbers above this, being divided by 6, there remains nothing, the cube root being 12. Thus the remainders of the higher cubes are to be added to 12, and not to 6; till you come to 18, when the remainder of the divifion muft be added to 18; and fo on *ad infinitum*.

Determinate number is that referred to fome given unit, as a ternary or three: whereas an indeterminate one is that referred to unity in general, and is called *quantity*.

Homogeneal numbers, are thofe referred to the fame unit; as thofe referred to different units are termed *heterogeneal*.

Whole numbers are others called *integers*.

Rational number, is one commenfurable with unity; as a number, incommenfurable with unity, is termed *irrational*, or a *furd*.

In the fame manner, a rational whole number is that whereof unity is an aliquot part; a rational broken number, that equal to fome aliquot part of unity; and a rational mixed number, that confifting of a whole number and a broken one.

Even number, that which may be divided into two equal parts without any fraction, as 6, 12, *&c.* The fum, difference, and product, of any number of even numbers, is always an even number.

An evenly even number, is that which may be meafured, or divided, without any remainder, by another even number, as 4 by 2.

An unevenly even number, when a number may be equally divided by an uneven number, as 20 by 5.

Uneven number, that which exceeds an even number, at leaft by unity, or which cannot be divided into two

two equal parts, as 3, 5, *&c.*

The ſum or difference of two uneven numbers makes an even number; but the factum of two uneven ones makes an uneven number.

If an even number be added to an uneven one, or if the one be ſubtracted from the other, in the former caſe the ſum, in the latter the difference, is an uneven number; but the factum of an even and uneven number is even.

The ſum of any even number of uneven numbers is an even number; and the ſum of any uneven number of uneven numbers is an uneven number.

Primitive or prime numbers, are thoſe diviſible only by unity, as 5, 7, *&c.* And prime numbers among themſelves, are thoſe which have no common meaſure beſides unity, as 12 and 19.

Perfect number, that whoſe aliquot parts added together make the whole number, as 6, 28; the aliquot parts of 6 being 3, 2, and 1=6; and thoſe of 28, being 14, 7, 4, 2, 1, =28.

Imperfect numbers, thoſe whoſe aliquot parts added together make either more or leſs than the whole. And theſe are diſtinguiſhed into abundant and defective: an inſtance in the former caſe is 12, whoſe aliquot parts 6, 4, 3, 2, 1, make 16; and in the latter caſe 16, whoſe aliquot parts 8, 4, 2, and 1, make but 15.

Plain number, that ariſing from the multiplication of two numbers, as 6, which is the product of 3 by 2; and theſe numbers are called the *ſides of the plane.*

Square number is the product of any number multiplied by itſelf; thus 4, which is the factum of 2 by 2, is a ſquare number.

Even ſquare number added to its root makes an even number.

Polygonal or polygonous numbers, the ſums of arithmetical progreſſions beginning with unity: theſe, where the common difference is 1, are called *triangular numbers;* where 2, *ſquare numbers;* where 3, *pentagonal numbers;* where 4, *hexagonal numbers;* where 5, *heptagonal numbers,* &c.

Pyramidal numbers, the ſums of polygonous numbers, collected after the ſame manner as the polygons themſelves, and not gathered out of arithmetical progreſſions, are called *firſt pyramidal numbers:* the ſums of the firſt pyramidals are called *ſecond pyramidals,* &c.

If they ariſe out of triangular numbers, they are called *triangular pyramidal numbers;* if out of pentagons, *firſt pentagonal pyramidals.*

From the manner of ſumming up polygonal numbers, it is eaſy to conceive how the prime pyramidal numbers are found, *viz.* $\frac{(a-2)n^3+3n^3-(a-5)n}{6}$ expreſſes all the prime pyramidals.

The following curious property of the number 9 deſerves to be remarked, That its products compoſe always either 9 or ſome leſſer product of 9; if you add together all the characters, of which any of the former products is compoſed. Thus, of 18, 27, 36, which are products of 9, you make 9 by adding 1 to 8, 2 to 7, 3 to 6. Thus 369 is a product alſo of 9; and if you add 3, 6, and 9, you make 18, a leſſer product of 9.

Golden NUMBER, See ASTRONOMY, nº 304—307.

NUMBERS, in poetry, oratory, &c. are certain meaſures, proportions, or cadences, which render a verſe, period, or ſong, agreeable to the ear,

Poetical numbers conſiſt in a certain harmony in the order, quantities, &c. of the feet and ſyllables, which make the piece muſical to the ear, and fit for ſinging, for which all the verſes of the ancients were intended. See POETRY.—It is of theſe numbers Virgil ſpeaks in his ninth Eclogne, when he makes Lycidas ſay, *Numeros memini, ſi verba tenerem;* meaning, that although he had forgot the words of the verſes, yet he remembered the feet and meaſure of which they were compoſed.

Rhetorical or proſaic numbers are a ſort of ſimple unaffected harmony, leſs glaring than that of verſe, but ſuch as is perceived and affects the mind with pleaſure.

The numbers are that by which the ſtyle is ſaid to be eaſy, free, round, flowing, &c. Numbers are things abſolutely neceſſary in all writing, and even in all ſpeech. Hence Ariſtotle, Tully, Quintilian, &c. lay down abundance of rules as to the beſt manner of intermixing dactyles, ſpondees, anapeſts, &c. in order to have the numbers perfect. The ſubſtance of what they have ſaid, is reducible to what follows. 1. The ſtyle becomes numerous by the alternate diſpoſition and temperature of long and ſhort ſyllables, ſo as that the multitude of ſhort ones neither render it too haſty, nor that of long ones too ſlow and languid: ſometimes, indeed, long and ſhort ſyllables are thrown together deſignedly without any ſuch mixture, to paint the ſlowneſs or celerity of any thing by that of the numbers; as in theſe verſes of Virgil:

Illi inter ſeſe magna vi brachia tollunt;

and

Radit iter liquidum, celeres neque commovet alas.

2. The ſtyle becomes numerous, by the intermixing words of one, two, or more ſyllables; whereas the too frequent repetition of monoſyllables renders the ſtyle pitiful and grating. 3. It contributes greatly to the numerouſneſs of a period, to have it cloſed by magnificent and well-ſounding words. 4. The numbers depend not only on the nobleneſs of the words in the cloſe, but of thoſe in the whole tenor of the period. 4. To have the period flow eaſily and equally; the harſh concurrence of letters and words is to be ſtudiouſly avoided, particularly the frequent meeting of rough conſonants; the beginning the firſt ſyllable of a word with the laſt of the preceding; the frequent repetition of the ſame letter or ſyllable; and the frequent uſe of the like ending words. Laſtly, the utmoſt care is to be taken leſt, in aiming at oratorial numbers, you ſhould fall into poetical ones; and inſtead of proſe, write verſe.

Book of NUMBERS, the fourth book of the Pentateuch, taking its denomination from its numbering the families of Iſrael.

A great part of this book is hiſtorical, relating to ſeveral remarkable paſſages in the Iſraelites march through the wilderneſs. It contains a diſtinct relation of their ſeveral movements from one place to another, or their 42 ſtages through the wilderneſs, and many other things, whereby we are inſtructed and confirmed

ed in some of the weightiest truths that have immediate reference to God and his providence in the world. But the greatest part of this book is spent in enumerating those laws and ordinances, whether civil or ceremonial, which were given by God, but not mentioned before in the preceding books.

NUMERAL LETTERS, those letters of the alphabet which are generally used for figures; as I, one; V, five; X, ten; L, fifty; C, a hundred; D, five hundred; M, a thousand, &c.

It is not agreed how the Roman numerals originally received their value. It has been supposed that the Romans used M to denote 1000, because it is the first letter of *mille*, which is Latin for 1000; and C to denote 100, because it is the first letter of *centum*, which is Latin for 100. It has also been supposed, that D being formed by dividing the old M in the middle, was therefore appointed to stand for 500, that is, half as much as the M stood for when it was whole; and that L being half a C, was, for the same reason, used to denominate 50. But what reason is there to suppose, that 1000 and 100 were the numbers which letters were first used to express? And what reason can be assigned why D, the first letter in the Latin word *decem*, ten, should not rather have been chosen to stand for that number, than for 500 because it had a rude resemblance to half an M? But if these questions could be satisfactorily answered, there are other numeral letters which have never yet been accounted for at all. These considerations render it probable, that the Romans did not, in their original intention, use letters to express numbers at all; the most natural account of the matter seems to be this:

The Romans probably put down a single stroke, I, for one, as is still the practice of those who score on a slate or with chalk: this stroke, I, they doubled, trebled, and quadrupled, to express 2, 3, and 4: thus, II. III. IIII. So far they could easily number the minums, or strokes, with a glance of the eye. But they presently found, that if more were added, it would soon be necessary to tell the strokes one by one: for this reason, when they came to 5, they expressed it by joining two strokes together in an acute angle thus, V; which will appear the more probable, if it be considered, that the progression of the Roman numbers is from 5 to 5, *i. e.* from the fingers on one hand to the fingers on the other.—Ovid has touched upon the original of this in his *Fastorum* lib. iii. and *Vitruv*. lib. c. 1. has made the same remark.

After they had made this acute angle V. for five, they added the single strokes to it to the number of 4, thus, VI. VII. VIII. VIIII. and then as the minums could not be further multiplied without confusion, they doubled their acute angle, by prolonging the two lines beyond their intersection thus, X. to denote two fives, or ten. After this they doubled, trebled, and quadrupled, this double acute angle thus, XX. XXX. XXXX. they then, for the same reason which induced them first to make a single and then to double it, joined two single strokes in another form, and instead of an acute angle, made a right angle L, to denote fifty. When this 50 was doubled, they then doubled the right angle thus ⊏, to denote 100, and having numbered this double right angle four times, thus ⊏⊏. ⊏⊏⊏. ⊏⊏⊏⊏; when they came to the fifth number, as before, they reverted it, and put a single stroke before it thus I⊐, to denote 500; and when this 500 was doubled, then they also doubled their double right angle, setting two double right angles opposite to each other, with a single stroke between them, thus ⊏I⊐ to denote 1000: when this note for 1000 had been four times repeated, then they put down I⊐⊐ for 5,000, ⊏⊏I⊐⊐ for 10,000, and I⊐⊐⊐ for 50,000, ⊏⊏⊏I⊐⊐⊐ for 100,000, I⊐⊐⊐⊐ for 500,000, and ⊏⊏⊏⊏I⊐⊐⊐⊐ for one million.

That the Romans did not originally write M for 1000, and C for 100, but square characters, as they are written above, we are expressly informed by Paulus Manutius; but the corners of the angles being cut off by the transcribers for dispatch, these figures were gradually brought into what are now numeral letters. When the corners of ⊏I⊐, were made round, it stood thus CIↃ, which is so near the Gothic m, that it soon deviated into that letter; so I⊐ having the corner made round, it stood thus IↃ, and then easily deviated into D. ⊏ also became a plain C by the same means; the single rectangle which denoted 50, was, without alteration, a capital L; the double acute angle was an X; the single acute angle a V consonant; and a plain single stroke, the letter I,; and thus these seven letters, M, D, C, L, X, V, I, became numerals.

NUMERATION, or NOTATION, in arithmetic, the art of expressing in characters any number proposed in words, or of expressing in words any number proposed in characters. See ARITHMETIC, p. 653.

NUMERICAL, NUMEROUS, or *Numeral*, something belonging to numbers; as numerical algebra is that which makes use of numbers, instead of letters of the alphabet.—Also numerical difference is that by which one man is distinguished from another. Hence a thing is said to be numerically the same, when it is so in the strictest sense of the word.

NUMIDA, in ornithology, a genus belonging to the order of gallinæ. On each side of the head there is a kind of coloured fleshy horn; and the beak is furnished with cere near the nostrils. There is but one species, the meleagris, or Guinea-hen; a native of Africa. It is of the size of the common hen, but with a longer neck. Its body is sloped like that of a partridge, and its colour is all over a dark grey, very beautifully spotted with small white specks; there is a black ring round the neck; its head is reddish, and it is blue under the eyes. They naturally herd together in large numbers, and breed up their young in common; the females taking care of the broods of others, as well as of their own. Barbot informs us, that in Guinea they are in flocks of 200 or 300, that perch in trees, and feed on worms and grasshoppers; that they are run down and taken by dogs; and that their flesh is tender and sweet, generally white, though sometimes black. They breed very well with us.

NUMIDIA, an ancient kingdom of Africa, bounded on the north by the Mediterranean Sea; on the south by Gætulia, or part of Libya Interior; on the west by the Mulucha, a river which separated it from Mauritania; and on the east by the Tusca, another river which bounded it in common with Africa Propria. Dr Shaw has rendered it probable, that the river which formerly went under the denominations of

Malva,

Numidia. *Malva*, *Malvana*, *Mulucha*, and *Molochath*, is the ſame with that now called Mullooiah by the Algerines; in which caſe, the kingdom of Numidia muſt have extended upwards of 500 miles in length: its breadth, however, cannot be ſo well aſcertained; but ſuppoſing it to have been the ſame with that of the preſent kingdom of Algiers, in the narroweſt part it muſt have been at leaſt 40 miles broad, and in the wideſt upwards of 100.

1 Ancient diviſion. This county included two diſtricts; one inhabited by the *Maſſyli*, and the other by the *Maſæſyli*; the latter being alſo called in after-times, *Mauritania Cæſarienſis*, and the former *Numidia Propria*. The country of the Maſſyli, or, as ſome call it, *Terra Metagonitis*, was ſeparated from the proper territory of Carthage by its eaſtern boundary the river Tuſca, and from the kingdom of the Maſæſyli, or Mauritania Cæſarienſis, by the river Ampſaga. It ſeems to correſpond with that part of the province of Conſtantina lying between the Zaine and the Wed al Kibeer, which is above 130 miles long, and more than 100 broad. The ſea-coaſt of this province is for the moſt part mountainous and rocky, anſwering to the appellation given to it by Abulfeda, viz. *El Edwaa*, *the high* or *lofty*. It is far from being equal in extent to the ancient country of the Maſæſyli, which, Strabo informs us, was yet inferior to the country of the Maſſyli. Its capital was Cirta, a place of very conſiderable note among the ancients.

2 Peopled by the deſcendants of Phut. The moſt celebrated antiquarians agree, that the tract, extending from the iſthmus of Suez to the lake Tritonis, was chiefly peopled by the deſcendants of Mizraim; and that the poſterity of his brother Put, or Phut, ſpread themſelves all over the country between that lake and the Atlantic ocean. To this notion Herodotus gives great countenance: for he tells us, that the Libyan Nomades, whoſe territories to the weſt were bounded by the Triton, agreed in their cuſtoms and manners with the Egyptians; but that the Africans from that river to the Atlantic Ocean, differed in almoſt all points from them. Ptolemy mentions a city called *Putea* near Adrametum; and Pliny, a river of Mauritania Tingitana, known by the name of *Fut*, or *Phut*; and the diſtrict adjacent to this river was called *Regio Phutenſis*, which plainly alludes to the name of *Phut*. That word ſignifies *ſcattered*, or *diſperſed*, which very well agrees with what Mela and Strabo relate of the ancient Numidians; ſo that we may, without any ſcruple, admit the Aborigines of this country to have been the deſcendants of Phut.

3 Great part of the hiſtory unknown. The hiſtory of Numidia, during many of the early ages, is buried in oblivion. It is probable, however, that as the Phœnicians were maſters of a great part of the country, theſe tranſactions had been recorded, and generally known to the Carthaginians. King Jarbas probably reigned here as well as in Africa Propria, if not in Mauritania, and other parts of Libya, when Dido began to build Byrſa. It appears from Juſtin, that about the age of Herodotus, the people of this country were called both *Africans* or *Libyans* and *Numidians*. Juſtin likewiſe intimates, that about this time the Carthaginians vanquiſhed both the Moors or Mauritanians, and Numidians; in conſequence of which they were excuſed from paying the tribute which had hitherto been demanded of them. Numidia.

After the concluſion of the firſt Punic war, the African troops carried on a bloody conteſt againſt their maſters the Carthaginians; and the moſt active in this rebellion, according to Diodorus Siculus, were a part of the Numidian nation named *Micatanians*. This ſo incenſed the Carthaginians, that after Hamilcar had either killed or taken priſoners all the mercenaries, he ſent a large detachment to ravage the country of thoſe Numidians. The commandant of that detachment executed his orders with the utmoſt cruelty, plundering the diſtrict in a terrible manner, and crucifying all the priſoners, without diſtinction, that fell into his hands. This filled the reſt with ſuch indignation and reſentment, that both they and their poſterity ever afterwards bore an implacable hatred to the Carthaginians.

In the time of the ſecond Punic war, Syphax, king of the Maſæſyli, entered into an alliance with the Romans, and gave the Carthaginians a conſiderable defeat. This induced Gala, king of the Maſſyli, to conclude a treaty with the Carthaginians, in conſequence of which his ſon Maſiniſſa marched at the head of a powerful army to give Syphax battle. The conteſt ended in favour of Maſiniſſa; 30,000 of the Maſſæſyli were put to the ſword, and Syphax driven into Mauritania; and the like bad ſucceſs attended Syphax in another engagement, where his troops were entirely defeated and diſperſed. 4 Hiſtory of Syphax and Maſiniſſa.

Gala dying whilſt his ſon Maſiniſſa was acting at the head of the Numidian troops ſent to the aſſiſtance of the Carthaginians in Spain, his brother Deſalces, according to the eſtabliſhed rules of ſucceſſion in Numidia, took poſſeſſion of the Maſſylian throne. That prince dying ſoon after his acceſſion, Capuſa his eldeſt ſon ſucceeded him. But he did not long enjoy his high dignity; for one Mezetulus, a perſon of the royal blood, but an enemy to the family of Gala, found means to excite a great part of his ſubjects to revolt. A battle ſoon took place between him and Capuſa; in which the latter was ſlain with many of the nobility, and his army entirely defeated. But tho' Mezetulus thus became poſſeſſed of the ſovereignty, he did not think proper to aſſume the title of *king*, but ſtyled himſelf guardian to Lacumaces, the ſurviving ſon of Deſalces, whom he graced with the royal title. To ſupport himſelf in his uſurpation, he married the dowager of Deſalces, who was Hannibal's niece, and conſequently of the moſt powerful family in Carthage. In order to attain the ſame end, he ſent ambaſſadors to Syphax, to conclude a treaty of alliance with him. In the mean time Maſiniſſa, receiving advice of his uncle's death, of his couſin's ſlaughter, and of Mezetulus's uſurpation, immediately paſſed over to Africa, and went to the court of Bocchar king of Mauritania, to ſolicit ſuccours. Bocchar, ſenſible of the great injuſtice done Maſiniſſa, gave him a body of 4000 Moors to eſcort him to his dominions. His ſubjects, having been appriſed of his approach, joined him upon the frontiers with a party of 500 men. The Moors, in purſuance of their orders, returned home, as ſoon as Maſiniſſa reached the confines of his kingdom. Notwithſtanding which, and the ſmall body that declared for him having accidentally met Lacumaces at Thapſus with an eſcort going to

Numidia. to implore Syphax's affiftance, he drove him into the town, which he carried by affault, after a faint refiftance. However, Lacumaces, with many of his men, found means to efcape to Syphax. The fame of this exploit gained Mafiniffa great credit, infomuch that the Numidians flocked to him from all parts, and, amongft the reft, many of his father Gala's veterans, who preffed him to make a fpeedy and vigorous pufh for his hereditary dominions. Lacumaces having joined Mezetulus with a reinforcement of Maffæfylians, which he had prevailed upon Syphax to fend to the affiftance of his ally, the ufurper advanced at the head of a numerous army to offer Mafiniffa battle; which that prince, though much inferior in numbers, did not decline. Hereupon an engagement enfued; which, notwithftanding the inequality of numbers, ended in the defeat of Lacumaces. The immediate confequence of this victory to Mafiniffa, was a quiet and peaceable poffeffion of his kingdom; Mezetulus and Lacumaces, with a few that attended them, flying into the territories of Carthage. However, being apprehenfive that he fhould be obliged to fuftain a war againft Syphax, he offered to treat Lacumaces with as many marks of diftinction as his father Gala had Defalces; provided that prince would put himfelf under his protection. He alfo promifed Mezetulus pardon, and a reftitution of all the effects forfeited by his treafonable conduct, if he would make his fubmiffion to him. Both of them readily complied with the propofal, and immediately returned home; fo that the tranquillity and repofe of Numidia would have been fettled upon a folid and lafting foundation, had not this been prevented by Afdrubal, who was then at Syphax's court. He infinuated to that prince, who was difpofed to live amicably with his neighbours, "That he was greatly miftaken, if he imagined Mafiniffa would be fatisfied with his hereditary dominions. That he was a prince of much greater capacity and ambition, than either his father Gala, his uncle Defalces, or any of his family. That he had difcovered in Spain marks of a moft rare and uncommon merit. And that, in fine, unlefs his rifing flame was extinguifhed before it came to too great a head, both the Maffæfylian and Carthaginian ftates would be infallibly confumed by it." Syphax, alarmed by thefe fuggeftions, advanced with a numerous body of forces into a diftrict, which had long been in difpute between him and Gala, but was then in poffeffion of Mafiniffa. This brought on a general action between thefe two princes; wherein the latter was totally defeated, his army difperfed, and he himfelf obliged to fly to the top of mount Balbus, attended only by a few of his horfe. Such a decifive battle at the prefent juncture, before Mafiniffa was fixed in his throne, could not but put Syphax into poffeffion of the kingdom of the Maffyli. Mafiniffa in the mean time made nocturnal incurfions from his poft upon mount Balbus, and plundered all the adjacent country, particularly that part of the Carthaginian territory contiguous to Numidia. This diftrict he not only thoroughly pillaged, but likewife laid wafte with fire and fword, carrying off from thence an immenfe booty, which was bought by fome merchants, who had put into one of the Carthaginian ports for that purpofe. In fine, he did the Carthaginians more damage, not only by committing fuch dreadful devaftations, but by maffacring and carrying into captivity vaft numbers of their fubjects on this occafion, than they could have fuftained in a pitched battle, or one campaign of a regular war. Syphax, at the preffing and reiterated inftances of the Carthaginians, fent Bocchar, one of his moft active commanders, with a detachment of 4000 foot, and 2000 horfe, to reduce this peftilent gang of robbers, promifing him a great reward if he could bring Mafiniffa either alive or dead. Bocchar, watching an opportunity, furprifed the Maffylians, as they were ftraggling about the country without any order or difcipline; fo that he took many prifoners, difperfed the reft, and purfued Mafiniffa himfelf, with a few of his men, to the top of the mountain where he had before taken poft. Confidering the expedition as ended, he not only fent many head of cattle, and the other booty that had fallen into his hands, to Syphax, but likewife all the forces, except 500 foot and 200 horfe. With this detachment he drove Mafiniffa from the fummit of the hill, and purfued him through feveral narrow paffes and defiles, as far as the plains of Clupea. Here he fo furrounded him, that all the Maffylians, except four, were put to the fword, and Mafiniffa himfelf, after having received a dangerous wound, efcaped with the utmoft difficulty. As this was effected by croffing a rapid river, in which attempt two of his four attendants perifhed in the fight of the detachment that purfued him, it was rumoured all over Africa, that Mafiniffa alfo was drowned; which gave inexpreffible pleafure to Syphax and the Carthaginians. For fome time he lived undifcovered in a cave, where he was fupported by the robberies of the two horfemen that had made their efcape with him. But having cured his wound by the application of fome medicinal herbs, he boldly began to advance towards his own frontiers, giving out publicly that he intended once more to take poffeffion of his kingdom. In his march he was joined by about 40 horfe, and, foon after his arrival amongft the Maffyli, fo many people flocked to him from all parts, that out of them he formed an army of 6000 foot, and 4000 horfe. With thefe forces, he not only reinftated himfelf in the poffeffion of his dominions, but likewife laid wafte the borders of the Maffæfyli. This fo irritated Syphax, that he immediately affembled a body of troops, and encamped very commodioufly upon a ridge of mountains between Cirta and Hippo. His army he commanded in perfon; and detached his fon Vermina, with a confiderable force, to take a compafs, and attack the enemy in the rear. In purfuance of his orders, Vermina fet out in the beginning of the night, and took poft in the place appointed him, without being difcovered by the enemy. In the mean time Syphax decamped, and advanced towards the Maffyli, in order to give them battle. When he had poffeffed himfelf of a rifing ground that led to their camp, and concluded that his fon Vermina muft have formed the ambufcade behind them, he began the fight. Mafiniffa being advantageoufly pofted, and his foldiers diftinguifhing themfelves in an extraordinary manner, the difpute was long and bloody. But Vermina unexpectedly falling upon their rear, and by this means obliging them to divide their forces, which were fcarce able before to oppofe the main body under Syphax,

Numidia. phax, they were soon thrown into confusion, and forced to betake themselves to a precipitate flight. All the avenues being blocked up, partly by Syphax, and partly by his son, such a dreadful slaughter was made of the unhappy Massyli, that only Masinissa himself, with 60 horse, escaped to the Lesser Syrtis. Here he remained, betwixt the confines of the Carthaginians and Garamantes, till the arrival of Lælius and the Roman fleet on the coast of Africa. What happened immediately after this junction with the Romans, belongs to the article ROME.

It will be sufficient therefore in this place to observe, that, by the assistance of Lælius, Masinissa at last reduced Syphax's kingdom. According to Zonaras, Masinissa and Scipio, before the memorable battle of Zama, by a stratagem deprived Hannibal of some advantageous posts; which, with a solar eclipse happening during the heat of the action, and not a little intimidating the Carthaginian troops, greatly contributed to the victory the Romans obtained. At the conclusion therefore of the second Punic war, he was amply rewarded by the Romans for the important services he had done them. As for Syphax, after the loss of his dominions, he was kept in confinement for some time at Alba; from whence being removed in order to grace Scipio's triumph, he died at Tibur in his way to Rome. Zonaras adds, that his corpse was decently interred; that all the Numidian prisoners were released; and that Vermina, by the assistance of the Romans, took peaceable possession of his father's throne. However, part of the Massæsylian kingdom had been before annexed to Masinissa's dominions, in order to reward that prince for his singular fidelity and close attachment to the Romans.

This seems to be countenanced by the epitomizer of Livy, who gives us sufficiently to understand, that Syphax's family, for a considerable term after the conclusion of the second Punic war, reigned in one part of Numidia. For he intimates, that Archobarzanes, Syphax's grandson, and probably Vermina's son, hovered with a powerful army of Numidians upon the Carthaginian frontiers a few years before the beginning of the third Punic war. This he seems to have done, either in order to cover them, or to enable the Carthaginians to make an irruption into Masinissa's territories. Cato, however, pretended that these forces, in conjunction with those of Carthage, had a design to invade the Roman dominions, which he urged as a reason to induce the conscript fathers to destroy the African republic.

Nothing is further requisite, in order to complete the history of this famous prince, than to exhibit to our readers view some points of his conduct towards the decline, and at the close, of life; the wise dispositions made after his death by Æmilianus, in order to the regulation of his domestic affairs; and some particulars relating to his character, genius, and habit of body, drawn from the most celebrated Greek and Roman authors.

By drawing a line of circumvallation around the Carthaginian army under Asdrubal, posted upon an eminence, Masinissa cut off all manner of supplies from them; which introduced both the plague and famine into their camp. As the body of Numidian troops employed in this blockade was not near so numerous as the Carthaginian forces, it is evident, that the line here mentioned must have been extremely strong, and consequently the effect of great labour and art. The Carthaginians, finding themselves reduced to the last extremity, concluded a peace upon the following terms, which Masinissa dictated to them: 1. That they should deliver up all deserters. 2. That they should recal their exiles, who had taken refuge in his dominions. 3. That they should pay him 5000 talents of silver within the space of 50 years. 4. That their soldiers should pass under the jugum, each of them carrying off only a single garment. As Masinissa himself, though between 80 and 90 years of age, conducted the whole enterprise, he must have been extremely well versed in fortification, and other branches of the military art. His understanding likewise he must have retained to the last. This happened a short time before the beginning of the third Punic war. See CARTHAGE.

5 Masinissa displeased with the Romans.

Soon after, the consuls landed an army in Africa, in order to lay siege to Carthage, without imparting to Masinissa their design. This not a little chagrined him, as it was contrary to the former practice of the Romans; who in the preceding war had communicated their intentions to him, and consulted him on all occasions. When, therefore, the consuls applied to him for a body of his troops to act in concert with their forces, he made answer, "That they should have a reinforcement from him when they stood in need of it." It could not but be provoking to him to consider, that after he had extremely weakened the Carthaginians, and even brought them to the brink of ruin, his pretended imperious friends should come to reap the fruits of his victory, without giving him the least intelligence of it.

6 But leaves every thing to the disposal of Æmilianus.

However, his mind soon returned to its natural bias, which was in favour of the Romans. Finding his end approaching, he sent to Æmilianus, then a tribune in the Roman army, to desire a visit from him. What he proposed by this visit, was to invest him with full powers to dispose of his kingdom and estate as he should think proper, for the benefit of his children. The high idea he had entertained of that young hero's abilities and integrity, together with his gratitude and affection for the family into which he was adopted, induced him to take this step. But, believing that death would not permit him to have a personal conference with Æmilianus upon this subject, he informed his wife and children in his last moments, that he had impowered him to dispose in an absolute manner of all his possessions, and to divide his kingdom amongst his sons. To which he subjoined, "I require, that whatever Æmilianus may decree, shall be executed as punctually as if I myself had appointed it by my will." Having uttered these words, he expired, at above 90 years of age.

This prince, during his youth, had met with strange reverses of fortune. However, says Appian, being supported by the divine protection, he enjoyed an uninterrupted course of prosperity for a long series of years. His kingdom extended from Mauritania to the western confines of Cyrenaica; from whence it appears, that he was one of the most powerful princes of Africa. Many of the inhabitants of this vast tract he civilized in a wonderful manner, teaching them to cul-

tivate their ſoil, and to reap thoſe natural advantages which the fertility of ſome parts of their country offered them. He was of a more robuſt habit of body than any of his cotemporaries, being bleſſed with the greateſt health and vigour; which was doubtleſs owing to his extreme temperance, and the toils he inceſſantly ſuſtained. We are informed by Polybius, that ſometimes he ſtood upon the ſame ſpot of ground from morning till evening, without the leaſt motion, and at others continued as long in a ſitting poſture. He would remain on horſeback for ſeveral days and nights together, without being ſenſible of the leaſt fatigue. Nothing can better evince the ſtrength of his conſtitution, than his youngeſt ſon, named *Stembal*, *Sthemba*, or *Stembanus*, who was but four years old at his deceaſe. Though 90 years of age, he performed all the exerciſes uſed by young men, and always rode without a ſaddle. Pliny tells us, that he reigned above 60 years. He was an able commander, and much facilitated the reduction of Carthage. Plutarch from Polybius obſerves, that the day after a great victory won over the Carthaginians, Maſiniſſa was ſeen ſitting at the door of his tent, eating a piece of brown bread. Suidas relates, that, to the laſt, he could mount his horſe without any aſſiſtance. According to Appian, he left a numerous well-diſciplined army, and an immenſe quantity of wealth, behind him.

Maſiniſſa, before his death, gave his ring to his eldeſt ſon Micipſa; but left the diſtribution of all his other effects and poſſeſſions amongſt his children, entirely to Æmilianus. Of 54 ſons that ſurvived him, only three were legitimate, to wit, Micipſa, Guluſſa, and Maſtanabal. Æmilianus, arriving at Cirta after he had expired, divided his kingdom, or rather the government of it, amongſt theſe three, though to the others he gave conſiderable poſſeſſions. To Micipſa, who was a prince of a pacific diſpoſition, and the eldeſt ſon, he aſſigned Cirta, the metropolis, for the place of his reſidence, in excluſion of the others. Guluſſa, the next to him, being a prince of a military genius, had the command of the army, and the tranſacting of all affairs relating to peace or war, committed to his care. And Manaſtabal, the youngeſt, had the adminiſtration of juſtice, an employment ſuitable to his education, allotted him. They enjoyed in common the immenſe treaſures Maſiniſſa had amaſſed, and were all of them dignified by Æmilianus with the royal title. After he had made theſe wiſe diſpoſitions, that young nobleman departed from Cirta, taking with him a body of Numidian troops, under the conduct of Guluſſa, to reinforce the Roman army, that was then acting againſt the Carthaginians.

Maſtanabal and Guluſſa died ſoon after their father, as appears from the expreſs teſtimony of Salluſt. We find nothing more remarkable of theſe princes, beſides what has been already related, than that the latter continued to aſſiſt the Romans in the third Punic war; and that the former was pretty well verſed in the Greek language. Micipſa therefore became ſole poſſeſſor of the kingdom of Numidia. In his reign, and the conſulate of M. Plautius Hypſæus and M. Fulvius Flaccus, according to Oroſius, a great part of Africa was covered with locuſts, which deſtroyed all the produce of the earth, and even devoured dry wood. But at laſt they were all carried by the wind into the African ſea, out of which being thrown in vaſt heaps upon the ſhore, a plague enſued, which ſwept away an infinite number of animals of all kinds. In Numidia only, periſhed 800,000 men, and in Africa Propria 200,000: amongſt the reſt, 30,000 Roman ſoldiers quartered in and about Utica for the defence of the laſt province. At Utica, in particular, the mortality raged to ſuch a degree, that 1500 dead bodies were carried out of one gate in a day. Micipſa had two ſons, Adherbal and Hiempſal, whom he educated in his palace, together with his nephew Jugurtha. That young prince was the ſon of Maſtanabal; but his mother having been only a concubine, Maſiniſſa had taken no great notice of him. However, Micipſa conſidering him as a prince of the blood, took as much care of him as he did of his own children.

7 History of Jugurtha.

Jugurtha poſſeſſed ſeveral eminent qualities, which gained him univerſal eſteem. He was very handſome, endued with great ſtrength of body, and adorned with the fineſt intellectual endowments. He did not devote himſelf, as young men commonly do, to a life of luxury and pleaſure. He uſed to exerciſe himſelf, with perſons of his age, in running, riding, hurling the javelin, and other manly exerciſes, ſuited to the martial genius of the Numidians; and though he ſurpaſſed all his fellow ſportſmen, there was not one of them but loved him. The chace was his only delight; but it was that of lions, and other ſavage beaſts. Salluſt, to finiſh his character, tells us, that he excelled in all things, and ſpoke very little of himſelf.

So conſpicuous an aſſemblage of fine talents and perfections, at firſt charmed Micipſa, who thought them an ornament to his kingdom. However, he ſoon began to reflect, that he was conſiderably advanced in years, and his children in their infancy; that mankind naturally thirſted after power, and that nothing was capable of making men run greater lengths than a vicious and unlimited ambition. Theſe reflections ſoon excited his jealouſy, and determined him to expoſe Jugurtha to a variety of dangers, ſome of which, he entertained hopes, might prove fatal to him. In order to this, he gave him the command of a body of forces which he ſent to aſſiſt the Romans, who were at that time beſieging Numantia in Spain. But Jugurtha, by his admirable conduct, not only eſcaped all thoſe dangers, but likewiſe won the eſteem of the whole army, and the friendſhip of Scipio, who ſent a high character of him to his uncle Micipſa. However, that general gave him ſome prudent advice in relation to his future conduct; obſerving, no doubt, in him certain ſparks of ambition, which, if lighted into a flame, he apprehended might one day be productive of the moſt fatal conſequences.

8 Is dreaded by king Maſiniſſa.

Before this laſt expedition, Micipſa had endeavoured to find out ſome method of taking him off privately; but his popularity amongſt the Numidians obliged that prince to lay aſide all thoughts of this nature. After his return from Spain the whole nation almoſt adored him. The heroic bravery he had ſhewn there, his undaunted courage, joined to the utmoſt calmneſs of mind, which enabled him to preſerve a juſt medium between a timorous foreſight and an impetuous raſhneſs, a circumſtance rarely to be met with in perſons of his age, and above all the advantageous teſtimonials of his conduct given by Scipio, attracted an univerſal

Numidia. versal esteem. Nay, Micipsa himself, charmed with the high idea the Roman general had entertained of his merit, changed his behaviour towards him; resolving, if possible, to win his affection by kindness. He therefore adopted him, and declared him joint heir with his two sons to the crown. Finding, some few years afterwards, that his end approached, he sent for all three to his bed-side; where, in the presence of the whole court, he desired Jugurtha to recollect with what extreme tenderness he had treated him, and consequently to consider how well he had deserved at his hands. He then intreated him to protect his children on all occasions; who, being before related to him by the ties of blood, were now by their father's bounty become his brethren. In order to fix him the more firmly in their interest, he likewise complimented him upon his bravery, address, and consummate prudence. He further insinuated, that neither arms nor treasures constitute the strength of a kingdom; but friends, who are neither won by arms nor gold, but by real services, and an inviolable fidelity. "Now where, (continued he), can we find better friends than in brothers? And how can that man who becomes an enemy to his relations, repose any confidence in, or depend upon strangers?" Then addressing himself to Adherbal and Hiempsal, "And you, (said he), I enjoin always to pay the highest reverence to Jugurtha. Endeavour to imitate, and if possible surpass, his exalted merit, that the world may not hereafter observe Micipsa's adopted son to have reflected greater glory upon his memory than his own children." Soon after, Micipsa, who, according to Diodorus, was a prince of an amiable character, expired. Though Jugurtha did not believe the king to speak his real sentiments with regard to him, yet he seemed extremely pleased with so gracious a speech, and made him an answer suitable to the occasion. However, that prince at the same time was determined within himself to put in execution the scheme he had formed at the siege of Numantia, which was suggested to him by some factious and abandoned Roman officers, with whom he there contracted an acquaintance. The purport of this scheme was, that he should extort the crown by force from his two cousins, as soon as their father's eyes were closed; which they insinuated might easily be effected by his own valour, and the venality of the Romans. Accordingly, a short time after the old king's death, he found means to assassinate Hiempsal in the city of Thirmida where his treasures were deposited, and drive Adherbal out of his dominions. That unhappy prince found himself obliged to fly to Rome, where he endeavoured to engage the conscript fathers to espouse his quarrel; but, notwithstanding the justice of his cause, they had not virtue enough effectually to support him. Jugurtha's embassadors, by distributing vast sums of money amongst the senators, brought them so far over, that a majority palliated his inhuman proceedings. This encouraged those ministers to declare, that Hiempsal had been killed by the Numidians on account of his excessive cruelty; that Adherbal was the aggressor in the late troubles, and that he was only chagrined because he could not make that havoc amongst his countrymen he would willingly have done. They therefore intreated the senate to form a judgment of Jugurtha's behaviour in Africa from his conduct at Numantia, rather than from the suggestions of his enemies. Upon which, by far the greatest part of the senate discovered themselves prejudiced in his favour. A few however, that were not lost to honour, nor abandoned to corruption, insisted upon bringing him to condign punishment. But as they could not prevail, he had the best part of Numidia allotted him, and Adherbal was forced to rest satisfied with the other.

9 Who nevertheless entrusts him with the care of his children.

10 One of whom he murders, and drives out the other.

11 Venality of the Romans.

Jugurtha finding now by experience, that every thing was venal at Rome, as his friends at Numantia had before informed him, thought he might pursue his towering projects without any obstruction from that quarter. He therefore, immediately after the last division of Micipsa's dominions, threw off the mask, and attacked his cousin by open force. As Adherbal was a prince of a pacific disposition, and almost in all respects the reverse of Jugurtha, he was by no means a match for him. The latter therefore pillaged the former's territories, stormed several of his fortresses, and over-ran a good part of his kingdom without opposition. Adherbal, depending on the friendship of the Romans, which his father in his last moments assured him would be a stronger support to him than all the troops and treasures in the universe, dispatched deputies to Rome to complain of these hostilities. But whilst he lost his time in sending thither fruitless deputations, Jugurtha overthrew him in a pitched battle, and soon after shut him up in Cirta. During the siege of this city, a Roman commission arrived there, in order to persuade both parties to an accommodation; but finding Jugurtha untractable, the commissioners returned home without so much as conferring with Adherbal. A second deputation, composed of senators of the highest distinction, with Æmilius Scaurus, president of the senate, at their head, landed some time after at Utica, and summoned Jugurtha to appear before them. That prince at first seemed to be under dreadful apprehensions, especially as Scaurus reproached him with his enormous crimes, and threatened him with the resentment of the Romans if he did not immediately raise the siege of Cirta. However, the Numidian by his address, and the irresistible power of gold, as was afterwards suspected at Rome, so mollified Scaurus, that he left Adherbal at his mercy. In fine, Jugurtha had at last Cirta surrendered to him; upon condition only, that he should spare the life of Adherbal. But the merciless tyrant, in violation of the laws of nature and humanity, as well as the capitulation, when he had got possession of the town, ordered him to be put to a most cruel death. The merchants likewise, and all the Numidians in the place capable of bearing arms, he caused, without distinction, to be put to the sword.

Every person at Rome inspired with any sentiments of humanity, was struck with horror at the news of this tragical event. However, all the venal senators still concurred with Jugurtha's ministers in palliating his enormous crimes. Notwithstanding which, the people, excited thereto by Caius Memmius their tribune, who bitterly inveighed against the venality of the senate, resolved not to let so flagrant an instance of villany go unpunished. This disposition in them induced the conscript fathers likewise to declare their intention to chastise Jugurtha. In order to this, an army was levied to invade Numidia, and the command of it given to the consul Calpurnius Bestia, a person of good abili-

Numidia.

abilities, but rendered unfit for the expedition he was to go upon by his infatiable avarice. Jugurtha being informed of the great preparations making at Rome to attack his dominions, fent his fon thither to avert the impending ftorm. The young prince was plentifully fupplied with money, which he had orders to diftribute liberally amongft the leading men. But Beftia, propofing to himfelf great advantages from an invafion of Numidia, defeated all his intrigues, and got a decree paffed, ordering him and his attendants to depart Italy in ten days, unlefs they were come to deliver up the king himfelf, and all his territories, to the republic by way of dedition. Which decree being notified to them, they returned without fo much as having entered the gates of Rome; and the conful foon after landed with a powerful army in Africa. For fome time he carried on the war there very brifkly, reduced feveral ftrongholds, and took many Numidians prifoners. But upon the arrival of Scaurus, a peace was granted Jugurtha upon advantageous terms. That prince coming from Vacca, the place of his refidence, to the Roman camp, in order to confer with Beftia and Scaurus, and the preliminaries of the treaty being immediately after fettled between them in private conferences, every body at Rome was convinced that the prince of the fenate and the conful had to their avarice facrificed the republic. The indignation therefore of the people in general, difplayed itfelf in the ftrongeft manner. Memmius alfo fired them with his fpeeches. It was therefore refolved to difpatch the prætor Caffius, a perfon they could confide in, to Numidia, to prevail upon Jugurtha to come to Rome, that they might learn from the king himfelf which of their generals and fenators had been feduced by the peftilent influence of corruption. Upon his arrival there, he found means to bribe one Bæbius Salca, a man of great authority amongft the plebeians, but of infatiable avarice, by whofe affiftance he efcaped with impunity. Nay, by the efficacy of gold, he not only eluded all the endeavours of the people of Rome to bring him to juftice, but likewife enabled Bomilcar, one of his attendants, to get Maffiva, an illegitimate fon of Micipfa, affaffinated in the ftreets of Rome. That young prince was advifed by many Romans of probity, well-wifhers to the family of Mafiniffa, to apply for the kingdom of Numidia; which coming to Jugurtha's ears, he prevented the application by this execrable ftep. However, he was obliged to leave Italy immediately.

Jugurtha had fcarce fet foot in Africa when he received advice, that the fenate had annulled the fhameful peace concluded with him by Beftia and Scaurus. Soon after, the conful Albinus tranfported a Roman army into Numidia, flattering himfelf with the hopes of reducing Jugurtha to reafon before the expiration of his confulate. In this, however, he found himfelf deceived; for that crafty prince, by various artifices fo amufed and impofed upon Albinus, that nothing of moment happened that campaign. This rendered him ftrongly fufpected of having betrayed his county, after the example of his predeceffors. His brother Aulus, who fucceeded him in the command of the army, was ftill more unfuccefsful; for after rifing from before Suthul, where the king's treafures were depofited, he marched his forces into a defile out of which he found it impoffible to extricate himfelf. He therefore was obliged to fubmit to the ignominious ceremony of paffing under the *jugum*, with all his men, and to quit Numidia entirely in ten days time, in order to deliver his troops from immediate deftruction. The avaricious difpofition of the Roman commander had prompted him to befiege Suthul, the poffeffion of which place he imagined would make him mafter of all the wealth of Jugurtha, and confequently paved the way to fuch a fcandalous treaty. However, this was declared void as foon as known at Rome, as being concluded without the authority of the people. The Roman troops retired into Africa Propria, which they had now reduced into the form of a Roman province, and there took up their winter-quarters.

Numidia.

In the mean time Caius Mamilius Limetanus, tribune of the people, excited the plebeians to inquire into the conduct of thofe perfons by whofe affiftance Jugurtha had found means to elude all the decrees of the fenate. This put the body of the people into a great ferment; which occafioned a profecution of the guilty fenators, that was carried on, for fome time, with the utmoft heat and violence. Lucius Metellus 12
the conful, during thefe tranfactions, had Numidia Metellus
affigned him for his province, and confequently was fent againft
appointed general of the army deftined to act againft Jugurtha.
Jugurtha. As he perfectly difregarded wealth, the Numidian found him fuperior to all his temptations; which was a great mortification to him. To this he joined all the other virtues which conftitute the great captain; fo that Jugurtha found him in all refpects inacceffible. That prince therefore was now forced to regulate his conduct according to the motions of Metellus, with the greateft caution, and to exert his utmoft bravery, in order to compenfate for that hitherto fo favourable expedient which now began to fail him. Marius, Metellus's lieutenant, being likewife a perfon of uncommon merit, the Romans reduced Vacca, a large opulent city, and the moft celebrated mart in Numidia. They alfo defeated Jugurtha in a pitched battle; overthrew Bomilcar, one of his generals, upon the banks of the Muthullus; and, in fine, forced the Numidian monarch to take fhelter in a place rendered almoft inacceffible by the rocks and woods with which it was covered. However, Jugurtha fignalifed himfelf in a furprifing manner, exhibiting all that could be expected from the courage, abilities, and attention of a confummate general, to whom defpair adminifters frefh ftrength, and fuggefts new lights. But his troops could not make head againft the Romans; they were again worfted by Marius, though they obliged Metellus to raife the fiege of Zama. Jugurtha therefore, finding his country every where ravaged, his moft opulent cities plundered, his fortreffes reduced, his towns burnt, vaft numbers of his fubjects put to the fword and taken prifoners, began to think ferioufly of coming to an accommodation with the Romans. His favourite 13
Bomilcar, in whom he repofed the higheft confidence, Who is be-
but who had been gained over to the enemy by Me- trayed by
tellus, obferving this difpofition, found it no difficult Bomilcar.
matter to perfuade him to deliver up his elephants, money, arms, horfes, and deferters, in whom the main ftrength of his army confifted, into the hands of the Romans. Some of thefe laft, in order to avoid the punifhment due to their crime, retired to Bocchus king of Mauritania, and lifted in his fervice. But Metellus ordering

Numidia.

ordering him to repair to Tifidium, a city of Numidia, there to receive farther directions, and he refufing a compliance with that order, hoftilities were renewed with greater fury than ever. Fortune now feemed to declare in favour of Jugurtha: he retook Vacca, and maffacred all the Roman garrifon, except Turpilius the commandant. However, foon after, a Roman legion feized again upon it, and treated the inhabitants with the utmoft feverity. About this time, one of Maftanabal's fons, named *Gauda*, whom Micipfa in his will had appointed to fucceed to the crown in cafe his two legitimate fons and Jugurtha died without iffue, wrote to the fenate in favour of Marius, who was then endeavouring to fupplant Metellus. That prince having his underftanding impaired by a declining ftate of health, fell a more eafy prey to the bafe and infamous adulation of Marius. The Roman, foothing his vanity, affured him, that as he was the next heir to the crown, he might depend upon being fixed upon the Numidian throne, as foon as Jugurtha was either killed or taken; and that this muft in a fhort time happen, when once he appeared at the head of the Roman army with an unlimited commiffion. Soon after, Bomilcar and Nabdalfa formed a defign to affaffinate Jugurtha, at the inftigation of Metellus; but this being detected, Bomilcar and moft of his accomplices fuffered death. The plot however had fuch an effect upon Jugurtha, that he enjoyed afterwards no tranquillity or repofe. He fufpected perfons of all denominations, Numidians as well as foreigners, of fome black defigns againft him. Perpetual terrors fat brooding over his mind; infomuch that he never got a wink of fleep but by ftealth, and often changed his bed in a low plebeian manner. Starting from his fleep, he would frequently fnatch his fword, and break out into the moft doleful cries: So ftrongly was he haunted by a fpirit of fear, jealoufy, and diftraction!

14 A confpiracy againft him.

Jugurtha having deftroyed great numbers of his friends on fufpicion of their having been concerned in the late confpiracy, and many more of them deferting to the Romans and Bocchus king of Mauritania, he found himfelf, in a manner, deftitute of counfellors, generals, and all perfons capable of affifting him in carrying on the war. This threw him into a deep melancholy, which rendered him diffatisfied with every thing, and made him fatigue his troops with a variety of contradictory motions. Sometimes he would advance with great celerity againft the enemy, and at others retreat with no fmall fwiftnefs from them. Then he refumed his former courage; but foon after defpaired either of the valour or fidelity of the forces under his command. All his movements therefore proved unfuccefsful, and at laft he was forced by Metellus to a battle. That part of the Numidian army which Jugurtha commanded, behaved with fome refolution; but the other fled at the firft onfet. The Romans therefore entirely defeated them, took all their ftandards, and made a few of them prifoners. Not many of them were flain in the action; fince, as Salluft obferves, the Numidians trufted more to their heels than to their arms for fafety in this engagement.

15 He is defeated by Metellus.

Metellus purfued Jugurtha and his fugitives to Thala. His march to this place being through vaft deferts, was extremely tedious and difficult. But being fupplied with leathern bottles and wooden veffels of all fizes taken from the huts of the Numidians, which were filled with water brought by the natives, who had fubmitted to him, he advanced towards that city. He had no fooner begun his march, than a moft copious fhower of rain, a thing very uncommon in thofe defarts, proved a great and feafonable refrefhment to his troops. This fo animated them, that upon their arrival before Thala, they attacked the town with fuch vigour, that Jugurtha, with his family, and treafures depofited therein, thought proper to abandon it. After a brave defence, it was reduced; the garrifon, confifting of Roman deferters, fetting fire to the king's palace, and confuming themfelves, together with every thing valuable to them, in the flames. Jugurtha, being now reduced to great extremities, retired into Gætulia, where he formed a confiderable corps. From thence he advanced to the confines of Mauritania; and engaged Bocchus king of that country, who had married his daughter, to enter into an alliance with him. In confequence of which, having reinforced his Gætulian troops with a powerful body of Mauritanians, he turned the tables upon Metellus, and obliged him to keep clofe within his entrenchments. Salluft informs us, that Jugurtha bribed Bocchus's minifters to influence that prince in his favour; and that having obtained an audience, he infinuated, that, fhould Numidia be fubdued, Mauritania muft be involved in its ruin, efpecially as the Romans feemed to have vowed the deftruction of all the thrones in the univerfe. In fupport of what he advanced, he produced feveral inftances very appofite to the point in view. However, the fame author feems to intimate, that Bocchus was determined to affift Jugurtha againft his enemies by the flight the Romans had formerly fhewn him. That prince, at the firft breaking out of the war, had fent ambaffadors to Rome, to propofe an offenfive and defenfive alliance to the republic; which, though of the utmoft confequence to it at that juncture, a few of the moft venal and infamous fenators, who were abandoned to corruption, prevented from taking effect. This undoubtedly wrought more powerfully upon Bocchus in favour of Jugurtha, than the relation he ftood in to him: For both the Moors and Numidians adapted the number of their wives to their circumftances, fo that fome had 10, 20, &c. to their fhare; their kings therefore were unlimited in this particular, and of courfe all degrees of affinity refulting to them from marriage had little force. It is obfervable, that the pofterity of thofe ancient nations have the fame cuftom prevailing amongft them at this day.

16 Marius fucceeds Metellus.

Such was the fituation of affairs in Numidia, when Metellus received advice of the promotion of Marius to the confulate. But, notwithftanding this injurious treatment, he generoufly endeavoured to draw off Bocchus from Jugurtha, though this would facilitate the reduction of Numidia for his rival. To this end ambaffadors were difpatched to the Mauritanian court, who intimated to Bocchus, "That it would be highly imprudent to come to a rupture with the Romans without any caufe at all; and that he had now a fine opportunity of concluding a moft advantageous treaty with them, which was much preferable to a war. To which they added, that whatever dependence he might place upon his riches, he ought

not

Numidia.

not to run the hazard of losing his dominions by embroiling himself with other states, when he could easily avoid this; that it was much easier to begin a war than to end it, which it was in the power of the victor alone to do; that, in fine, he would by no means consult the interest of his subjects if he followed the desperate fortunes of Jugurtha." To which Bocchus replied, "That for his part there was nothing he wished for more than peace; but that he could not help pitying the deplorable condition of Jugurtha; that if the Romans, therefore, would grant that unfortunate prince the same terms they had offered him, he would bring about an accommodation." Metellus let the Mauritanian monarch know, that it was not in his power to comply with what he desired. However, he took care to keep up a private negotiation with him till the new consul Marius's arrival. By this conduct he served two wise ends. First, he prevented thereby Bocchus from coming to a general action with his troops; which was the very thing Jugurtha desired, as hoping that this, whatever the event might be, would render a reconciliation betwixt him and the Romans impracticable. Secondly, this inaction enabled him to discover something of the genius and disposition of the Moors; a nation, of whom the Romans, till then, had scarce formed any idea; which, he imagined, might be of no small service, either to himself or his successors, in the future prosecution of the war.

Jugurtha, being informed, that Marius, with a numerous army, was landed at Utica, advised Bocchus to retire, with part of the troops, to some place of difficult access, whilst he himself took post upon another inaccessible spot with the remaining corps. By this measure, he hoped the Romans would be obliged to divide their forces, and consequently be more exposed to his efforts and attacks. He likewise imagined, that seeing no formidable body appear, they would believe the enemy in no condition to make head against them; which might occasion a relaxation of discipline, the usual attendant of a too great security, and consequently produce some good effect. However, he was disappointed in both these views. For Marius, far from suffering a relaxation of discipline to take place, trained up his troops, which consisted chiefly of new levies, in so perfect a manner, that they were soon equal in goodness to any consular army that ever appeared in the field. He also cut off great numbers of the Gætulian marauders, defeated many of Jugurtha's parties, and had like to have taken that

17 He gains a great advantage over Jugurtha.

prince himself near the city of Cirta. These advantages, though not of any great importance, intimidated Bocchus, who now made overtures for an accommodation; but the Romans, not being sufficiently satisfied of his sincerity, gave no great attention to them. In the mean time Marius pushed on his conquests, reducing several places of less note, and at last resolved to besiege Capsa. That this enterprize might be conducted with the greater secrecy, he suffered not the least hint of his design to transpire, even amongst any of his officers. On the contrary, in order to blind them, he detached A. Manlius, one of his lieutenants, with some light-armed cohorts, to the city of Lares, where he had fixed his principal magazine, and deposited the military chest. Before Manlius left the camp, that he might the more effectually amuse him, he intimated, that himself with the army should take the same route in a few days: but instead of that, he bent his march towards the Tanais, and in six days time arrived upon the banks of that river. Here he pitched his tents for a short time, in order to refresh his troops; which having done, he advanced to Capsa, and made himself master of it. As the situation of this city rendered it extremely commodious to Jugurtha, whose plan of operations, ever since the commencement of the war, it had exceedingly favoured, he levelled it with the ground after it had been delivered up to the soldiers to be plundered. The citizens likewise, being more strongly attached to that prince than any of the other Numidians, on account of the extraordinary privileges he indulged them with, and of course bearing a more implacable hatred to the Romans, he put to the sword or sold for slaves. The true motive of the consul's conduct on this occasion seems here to be assigned; though we are told by Sallust, in conformity to the Roman genius, that neither avarice nor resentment prompted him to so barbarous an action, but only a desire to strike a terror into the Numidians.

The Numidians, ever after this exploit, dreaded the very name of Marius; who now, in his own opinion, had eclipsed the glory of all his predecessor's great achievements, particularly the reduction of Thala, a city, in strength and situation, nearly resembling Capsa. Following his blow, he gradually presented himself before most of the places of strength in the enemy's country; many of which either opened their gates, or were abandoned, at his approach, being terrified with what had happened to the unfortunate citizens of Capsa. Others taking by force, he laid in ashes; and in short, filled the greatest part of Numidia with blood, horror, and confusion. Then, after an obstinate defence, he reduced a castle that seemed impregnable, seated not far from Mulucha, where Jugurtha kept part of his treasures. In the mean time, Jugurtha not being able to prevail upon Bocchus, by his repeated solicitations, to advance into Numidia, where he found himself greatly pressed, was obliged to have recourse to his usual method of bribing the Mauritanian ministers, in order to put that prince in motion. He also promised him a third part of his kingdom, provided they could either drive the Romans out of Africa, or get all the Numidian dominions confirmed to him by treaty.

So considerable a cession could not fail of engaging Bocchus to support Jugurtha with his whole power. The two African monarchs therefore, having joined their forces, surprised Marius near Cirta as he was going into winter-quarters. The Roman general was so pushed on this occasion, that the barbarians thought themselves certain of victory, and doubted not but they should be able to extinguish the Roman name in Numidia. But their incaution and too great security enabled Marius to give them a total defeat; which was 18 Jugurtha entirely defeated.
followed four days after by so complete an overthrow, that their numerous army, consisting of 90,000 men, by the accession of a powerful corps of Moors, commanded by Bocchus's son Volux, was entirely ruined. Sylla, Marius's lieutenant, most eminently distinguished himself in the last action, which laid the foundation of

of his future greatneſs. Bocchus, now looking upon Jugurtha's condition as deſperate, and not being willing to run the riſk of loſing his dominions, ſhewed a

19 Bocchus delivers up Jugurtha to the Romans

diſpoſition to clap up a peace with Rome. However, the republic gave him to underſtand, that he muſt not expect to be ranked amongſt its friends, till he had delivered up into the conſul's hands Jugurtha, the inveterate enemy of the Roman name. The Mauritanian monarch, having entertained an high idea of an alliance with that ſtate, reſolved to ſatisfy it in this particular; and was confirmed in his reſolution by one Dabar, a Numidian prince, the ſon of Maſſugrada, and deſcended by his mother's ſide from Maſiniſſa. Being cloſely attached to the Romans, and extremely agreeable to Bocchus on account of his noble diſpoſition, he defeated all the intrigues of Aſpar, Jugurtha's miniſter. Upon Sylla's arrival at the Mauritanian court, the affair there ſeemed to be entirely ſettled. However, Bocchus, who was for ever projecting new deſigns, and, like the reſt of his countrymen, in the higheſt degree perfidious, debated within himſelf, whether he ſhould ſacrifice Sylla or Jugurtha, who were both then in his power. He was a long time fluctuating with uncertainty, and combated by a contrariety of ſentiments. The ſudden changes, which diſplayed themſelves in his countenance, his air, and his whole perſon, evidently ſhewed how ſtrongly his mind was agitated. But at laſt he returned to his firſt deſign, to which the bias of his mind ſeemed naturally to lead him. He therefore delivered up Jugurtha into the hands of Sylla, to be conducted to Marius; who, by that ſucceſsful event, happily terminated this dangerous war. The kingdom of Numidia was now reduced to a new form: Bocchus, for his important ſervices, had the country of the Maſſæſyli, contiguous to Mauritania, aſſigned him; which, from this time, took the name of *New Mauritania*. Numidia Propria, or the country of the Maſſyli, was divided into three parts; one of which was given to Hiempſal, another to Mandreſtal, both deſcendants of Maſiniſſa; and the third the Romans annexed to Africa Propria, or the Roman province adjacent to it. What became of Jugurtha after he had graced Marius's triumph, at which ceremony he was led in chains, together with his two ſons, through the ſtreets of Rome, our readers will find related at large in a former part of this work.

20 Tranſactions after the death of Jugurtha.

Jugurtha's two ſons ſurvived him, but ſpent their lives in captivity at Venuſia. However, one of them, named *Oxyntas*, was, for a ſhort time, releaſed from his confinement by Aponius, who beſieged Acerræ in the war between the Romans and the Italian allies. That general brought this prince to his army, where he treated him as king, in order to draw the Numidian forces off from the Roman ſervice. Accordingly thoſe Numidians no ſooner heard that the ſon of their old king was fighting for the allies, than they began to deſert by campanies; which obliged Julius Cæſar the conſul to part with all his Numidian cavalry, and ſend them back into Africa. Some few years after this event, Pompey defeated Cneius Domitius Ahenobarbus, and Hiarbas, one of the kings of Numidia, killing 17,000 of their men upon the ſpot. Not ſatisfied with this victory, that general purſued the fugitives to their camp, which he ſoon forced, put Domitius to the ſword, and took Hiarbas priſoner. He then reduced that part of Numidia which belonged to Hiarbas, who ſeems to have ſucceeded Mandreſtal abovementioned; and gave it to Hiempſal, a neighbouring Numidian prince, deſcended from Maſiniſſa, who had always oppoſed the Marian faction.

21 Cæſar inſults Juba.

Suetonius informs us, that a diſpute happened between Hiempſal and one Maſintha, a noble Numidian, whom, it is probable, he had in ſome reſpect injured when Julius Cæſar firſt began to make a figure in the world. The ſame author adds, that Cæſar warmly eſpouſed the cauſe of Maſintha, and even groſsly inſulted Juba, Hiempſal's ſon, when he attempted to vindicate his father's conduct on this occaſion. He pulled him by the beard, than which a more unpardonable affront could not be offered to an African. In ſhort, he ſcreened Maſintha from the inſults and violence of his enemies; from whence a reaſon may be aſſigned for Juba's adhering ſo cloſely afterwards to the Pompeian faction.

22 Juba defeats one of Cæſar's lieutenants.

In conſequence of the indignity Cæſar had offered Juba, and the diſpoſition it had occaſioned, that prince did Cæſar great damage in the civil wars betwixt him and Pompey. By a ſtratagem he drew Curio, one of his lieutenants, to a general action, which it was his intereſt at that time to have avoided. He cauſed it to be given out all over Africa Propria and Numidia, that he was retired into ſome remote country at a great diſtance from the Roman territories. This coming to Curio's ears, who was then beſieging Utica, it hindered him from taking the neceſſary precautions againſt a ſurpriſe. Soon after, the Roman general receiving intelligence that a ſmall body of Numidians was approaching his camp, he put himſelf at the head of his forces in order to attack them, and, for fear they ſhould eſcape, began his march in the night, looking upon himſelf as ſure of victory. Some of their advanced poſts he ſurpriſed aſleep, and cut them to pieces; which ſtill farther animated him. In ſhort, about day-break he came up with the Numidians, whom he attacked with great bravery, though his men were then faſting, and vaſtly fatigued by their forced and precipitate march. In the mean time, Juba, who, immediately after the propagation of the rumour abovementioned, had taken care to march privately, with the main body of the Numidian army, to ſupport the detachment ſent before to decoy Curio, advanced to the relief of his men. The Romans had met with a great reſiſtance before he appeared; ſo that he eaſily broke them, killed Curio, with a great part of his troops, upon the ſpot, purſued the reſt to their camp, which he plundered, and took many of them priſoners. Moſt of the fugitives, who endeavoured to make their eſcape on board the ſhips in the port of Utica, were either ſlain by the purſuers, or drowned. The remainder fell into the hands of Varus, who would have ſaved them; but Juba, who arrogated to himſelf the honour of this victory, ordered moſt of them to be put to the ſword.

23 Juba overthrown by Cæſar.

This victory infuſed new life and vigour into the Pompeian faction, who thereupon conferred great honours upon Juba, and gave him the title of *king of all Numidia*. But Cæſar and his adherents declared him an enemy to the ſtate of Rome, adjudging to Bocchus and Bogud, two African princes entirely in their intereſt,

tereſt, the ſovereignty of his dominions. Juba afterwards, uniting his forces with thoſe of Scipio, reduced Cæſar to great extremities, and would in all probability have totally ruined him, had he not been relieved by Publius Sittius. That general, having formed a conſiderable corps, conſiſting of Roman exiles, and Mauritanian troops ſent him by Bocchus, according to Dio, or, as Cæſar will have it, Bogud, made an irruption into Gætulia and Numidia, whilſt Juba was employed in Africa Propria. As he ravaged theſe countries in a dreadful manner, Juba immediately returned with the beſt part of his army, to preſerve them from utter deſtruction. However, Cæſar knowing his horſe to be afraid of the enemy's elephants, did not think proper to attack Scipio in the abſence of the Numidian, till his own elephants, and a freſh reinforcement of troops, hourly expected, arrived from Italy. With this acceſſion of ſtrength, he imagined himſelf able to give a good account, both of the Roman forces with which he was to cope, and the barbarians. In the mean time Scipio diſpatched reiterated expreſſes to Juba to haſten to his aſſiſtance; but could not prevail upon him to move out of Numidia, till he had promiſed him the poſſeſſion of all the Roman dominions in Africa, if they could from thence expel Cæſar. This immediately put him in motion; ſo that, having ſent a large detachment to make head againſt Sittius, he marched with the reſt of his troops to aſſiſt Scipio. However, Cæſar at laſt overthrew Scipio, Juba, and Labienus, near the town of Thapſus, and forced all their camps. As Scipio was the firſt ſurpriſed and defeated, Juba fled into Numidia, without waiting for Cæſar's approach; but the body of the Numidians detached againſt Sittius, having been broken and diſperſed by that general, none of his ſubjects there would receive him. Abandoned therefore to deſpair, he ſought death in a ſingle combat with Petreius, and, having killed him, cauſed himſelf to be diſpatched by one of his ſlaves.

24
Numidia reduced to the form of a province.

After this deciſive action, and the reduction of Africa Propria, Cæſar made himſelf maſter of Numidia, which he reduced to a Roman province, appointing Criſpus Salluſtius to govern it in quality of proconſul, with private inſtructions to pillage and plunder the inhabitants, and, by that means, put it out of their power ever to ſhake off the Roman yoke. However, Bocchus and Bogud ſtill preſerved a ſort of ſovereignty in the country of the Maſſæſyli and Mauritania, ſince the former of thoſe princes, having deſerted Cæſar, ſent an army into Spain to aſſiſt the Pompeians; and the latter, with his forces, determined victory to declare for Cæſar at the ever memorable battle of Munda. Bogud, afterwards ſiding with Anthony againſt Octavius, ſent a body of forces to aſſiſt him in Spain; at which time the Tingitanians revolting from him, Bocchus, with an army compoſed of Romans in the intereſt of Octavius, who paſſed over from Spain into Africa, and his own ſubjects, poſſeſſed himſelf of Mauritania Tingitana. Bogud fled to Antony; and Octavius, after the concluſion of the war, honoured the inhabitants of Tingi with all the privileges of Roman citizens. He likewiſe confirmed Bocchus king of Mauritania Cæſarienſis, or the country of the Maſſæſyli, in the poſſeſſion of Tingitania, which he had conquered, as a reward for his important ſervices. In this he imitated the example of his great predeceſſor Julius Cæſar, who divided ſome of the fruitful plains of Numidia among the ſoldiers of P. Sittius, who had conquered great part of that country, and appointed Sittius himſelf ſovereign of that diſtrict. Sittius, as has been intimated above, having taken Cirta, killed Sabura Juba's general, entirely diſperſed his forces, and either cut off or taken priſoners moſt of the Pompeian fugitives that eſcaped from the battle of Thapſus, highly deſerved to be diſtinguiſhed in ſo eminent a manner. After Bocchus's death, Mauritania and the Maſſæſylian Numidia were, in all reſpects, conſidered as Roman provinces.

NUMISMATOGRAPHIA, a term uſed for the deſcription and knowledge of ancient coins and medals, whether of gold, ſilver, or braſs. See COINS and MEDALS.

NUMITOR, the ſon of Procas king of Alba, and the brother of Amulius. Procas dying made him and Amulius joint heirs to the crown, on condition of their reigning annually by turns: but Amulius, on getting poſſeſſion of the throne, excluded Numitor, whoſe ſon Lauſus he ordered to be put to death, and obliged Rhea Sylvia, Numitor's only daughter, to become a veſtal. This princeſs becoming pregnant, declared that ſhe was with child by the god Mars; and afterwards brought forth Rhemus and Romulus, who at length killed Amulius, and reſtored Numitor to the throne, 754 B. C.

NUMMUS, a piece of money otherwiſe called *ſeſtertius*.

NUN, a woman, in ſeveral Chriſtian countries, who devotes herſelf, in a cloiſter or nunnery, to a religious life. See the article MONK.

There were women, in the ancient Chriſtian church, who made public profeſſion of virginity, before the monaſtic life was known in the world, as appears from the writings of Cyprian and Tertullian. Theſe, for diſtinction's ſake, are ſometimes called *eccleſiaſtical virgins*, and were commonly enrolled in the canon or matricula of the church. They differed from the monaſtic virgin chiefly in this, that they lived privately in their fathers houſes, whereas the others lived in communities: but their profeſſion of virginity was not ſo ſtrict as to make it criminal in them to marry afterwards, if they thought fit. As to the conſecration of virgins, it had ſome things peculiar in it: it was uſually performed publicly in the church by the biſhop. The virgin made a public profeſſion of her reſolution, and then the biſhop put upon her the accuſtomed habit of ſacred virgins. One part of this habit was a veil, called the *ſacrum velamen;* another was a kind of mitre or coronet worn upon the head. At preſent, when a woman is to be made a nun, the habit, veil, and ring of the candidate are carried to the altar; and ſhe herſelf, accompained by her neareſt relations, is conducted to the biſhop, who, after maſs and an anthem, the ſubject of which is, "that ſhe ought to have her lamp lighted, becauſe the bridegroom is coming to meet her, pronounces the benediction: then ſhe riſes up, and the biſhop conſecrates the new habit, ſprinkling it with holy-water. When the candidate has put on her religious habit, ſhe preſents herſelf before the biſhop, and ſings, on her knees, *Ancilla Chriſti ſum*, &c.; then ſhe receives the veil, and afterwards the ring, by

by which ſhe is married to Chriſt; and laſtly, the crown of virginity. When ſhe is crowned, an anathema is denounced againſt all who ſhall attempt to make her break her vows.

NUNCIO, or Nuntio, an ambaſſador from the pope to ſome Catholic prince or ſtate, or a perſon who attends on the pope's behalf at a congreſs, or an aſſembly of ſeveral ambaſſadors.

NUNCUPATIVE, in the ſchools, ſomething that is only nominal, or has no exiſtence but in name.

Nuncupative *Will* or *Teſtament*, a will made verbally, and not put in writing. See the articles Will and Testament.

NUNDINA, a godeſs among the ancient Heathens, ſuppoſed to have the care of the purification of infants. And becauſe male-infants were purified nine days after their birth, her name is derived from nonus, or the ninth, though female-infants were purified the eighth day; which purification was called *luſtration* by the Romans.

NUNDINAL, (nundinalis,) a name which the Romans gave to the eight firſt letters of the alphabet, uſed in their kalendar.

This ſeries of letters, A, B, C, D, E, F, G, H, is placed and repeated ſucceſſively from the firſt to the laſt day of the year: one of theſe always expreſſed the market-days, or the aſſemblies called *nundinæ, quaſi novendinæ*, becauſe they returned every nine days. The country people, after working eight days ſucceſſively, came to town the ninth, to ſell their ſeveral commodities, and to inform themſelves of what related to religion and goverment. Thus the nundinal day being under A on the firſt, ninth, ſeventeenth, and twenty-fifth days of January, &c. the letter D will be the nundinal letter of the year following. Theſe nundinals bear a very great reſemblance to the dominical letters, which return every eight days, as the nundinals did every nine.

NUPTIAL rites, the ceremonies attending the ſolemnization of marriage, which are different in different ages and countries.

NUREMBERG, an imperial city of Germany, capital of a teritory of the ſame name, ſituated in E. Long. 11°, N. Lat. 49. 30. It ſtands on the Regnitz, over which it has ſeveral bridges, both of wood and ſtone, at the bottom of a hill, 60 miles from Augſburg, 87 from Munich, 46 from Wurtzburg, and 50 from Ratiſbon; and is thought by ſome to be the Segodunum, and by others the Caſtrum Noricum, of the ancients. It is large and well built, but not very populous. Its fortifications are a double wall, flanked with towers mounting cannon, and a deep ditch. The magiſtrates, and moſt of the inhabitants, are Lutherans. There are a great many churches and chapels in it. In that of St Sebald is a braſs monument of the ſaint; and a picture, repreſenting the creation of the world, by the celebrated Albert Durer, who was a native of the town; but the fineſt church in the town is that of St Giles. In that of the Holy Ghoſt are kept moſt of the jewels of the empire, together with the pretended ſpear with which our Saviour's ſide was pierced, a thorn of his crown, and a piece of the manger wherein he was laid. Here are alſo a great many hoſpitals, one in particular for foundlings, and another for pilgrims; with a gymnaſium, an anatomical theatre, a granary, a fine public library, the old imperial fortreſs or caſtle, ſome remains of the old citadel of the burgraves of Nuremberg, ſeveral Latin ſchools, an academy of painting, a well furniſhed arſenal, a teutonic houſe in which the Roman-catholic ſervice is tolerated, and a mint. Mr Keyſler ſays, there are upwards of 500 ſtreets in it, about 140 fountains, 16 churches, 44 religious houſes, 12 bridges, 10 market-places, and 25000 inhabitants; and that its territories, beſides the capital and four other towns, contains above 500 villages, and about 160 mills on the Regnitz. The trade of this city, though upon the decline, is ſtill very great, many of its manufactures being ſtill exported to all parts of the world; among which may be reckoned a great variety of curious toys in ivory, wood, and metal. The city has alſo diſtinguiſhed itſelf in the arts of painting and engraving. When the emperor Henry VI. aſſiſted at a tournament in Nuremberg, he raiſed 38 burghers to the degree of nobility, the deſcendants of whom are called *patricians*, and have the government of the city entirely in their hands; the whole council, except eight maſters of companies, who are ſummoned only on extraordinary occcaſions, conſiſting of them. Among the fine braſs cannon in the arſenal, is one that is charged at the breech, and may be fired eight times in a minute; and two that carry balls of eighty pounds. The city keeps, in conſtant pay, ſeven companies, conſiſting each, in time of peace, of 100 men, but, in time of war, of 185; two troops of cuiraſſiers, each conſiſting of 85 men; and two companies of invalids. There are alſo 24 companies of burghers, well armed and diſciplined. On the new bridge, which is ſaid to have coſt 100,000 guilders, are two pyramids, on the top of one of which is a dove with an olive branch in her bill, and on the other an imperial black eagle. Muſic alſo flouriſhes greatly in Nuremberg; and thoſe who delight in mechanic arts and manufactures, cannot any where better gratify their curioſity. As an imperial city, it has a ſeat and voice at the diets of the empire and circle, paying to a Roman month one ſeventh part of the common impoſts of the circle, and to the chamber of Wetzlar 812 rix-dollars, each term. The territory belonging to the city is pretty large, containing, beſides two conſiderable foreſts of pine, called the *Sibald* and *Laurence foreſts*, ſeveral towns and villages.

NURSERY, in gardening, is a piece of land ſet apart for raiſing and propagating all ſorts of trees and plants to ſupply the garden and other plantations.

NURSING of children. See Lactatio.

The following obſervations are ſaid to be the reſult of long experience. A child, when it comes into the world, is almoſt a round ball; it is the nurſe's part to aſſiſt nature, in bringing it to a proper ſhape. The child ſhould be laid (the firſt month) upon a thin matraſs, rather longer than the child, which the nurſe will keep upon her lap, that the child may always lie ſtraight, and only ſit up as the nurſe ſlants the matraſs. To ſet a child quite upright before the end of the firſt month, hurts the eyes, by making the white part of the eye appear below the upper eye-lid. Afterwards the nurſe will begin to ſet it up and dance it

An. Reg. vol. vi. p. 130.

it by degrees. The child muft be kept as dry as poffible.

The cloathing fhould be very light, and not much longer than the child, that the legs may be got at with eafe, in order to have them often rubbed in the day with a warm hand or flannel, and in particular the infide of them.

Rubbing a child all over takes off fcurf, and makes the blood circulate. The breaft fhould be rubbed with the hands, one one way, and the other the other way, night and morning at leaft.

The ankle-bones and infide of the knees fhould be rubbed twice a-day; this will ftrengthen thofe parts, and make the child ftretch its knees and keep them flat, which is the foundation of an erect and graceful perfon.

A nurfe ought to keep a child as little in her arms as poffible, left the legs fhould be cramped, and the toes turned inwards. Let her always keep the child's legs loofe. The oftener the pofture is changed, the better.

Toffing a child about, and exercifing it in the open air in fine weather, is of the greateft fervice. In cities, children are not to be kept in hot rooms, but to have as much air as poffible.

Want of exercife is the caufe of large heads, weak and knotted joints, a contracted breaft, which occafions coughs and ftuffed lungs, an ill-fhaped perfon, and waddling gait, befides a numerous train of other i lls.

The child's flefh is to be kept perfectly clean, by conftantly wafhing its limbs, and likewife its neck and ears; beginning with warm water, till by degrees it will not only bear, but like, to be wafhed with cold.

Rifing early in the morning is good for all children, provided they awake of themfelves, which they generally do; but they are never to be waked out of their fleep, and as foon as poffible to be brought to regular fleeps in the day.

When laid in bed or cradle, their legs are always to be laid ftraight.

Children, till they are two or three years old, they muft never be fuffered to walk long enough at a time to be weary.

Girls might be trained to the proper management of children, if a premium were given in free-fchools, workhoufes, &c. to thofe that brought up the fineft child to one year old.

If the mother cannot fuckle the child, get a wholefome cheerful woman, with a young milk, who has been ufed to tend young children. After the firft fix months, fmall broths, and innocent foods of any kind, may do as well as living wholly upon milk.

A principal thing to be always attended to is, to give young children conftant exercife, and to keep them in a proper pofture.

With regard to the child's drefs in the day, let it be a fhirt; a petticoat of fine flannel, two or three inches longer than the child's feet, with a dimitytop (commonly called a *bodice-coat*), to tie behind; over that a furcingle made of fine buckram, two inches broad, covered over with fattin or fine ticken, with a ribbon faftened to it to tie it on, which anfwers every purpofe of ftays, and has none of their inconveniences.

Over this put a robe, or a flip and frock, or whatever you like beft; provided it is faftened behind, and not much longer than the child's feet, that their motions may be ftrictly obferved.

Two caps are to be put on the head, till the child has got moft of its teeth.

The child's drefs for the night may be a fhirt, a blanket to tie on, and a thin gown to tie over the blanket.

NUSANCE, in law, a thing done to the annoyance of another.

Nufances are either public or private.—A public nufance is an offence againft the public in general, either by doing what tends to the annoyance of all the king's fubjects, or by neglecting to do what the common good requires: in which cafe, all annoyances and injuries to ftreets, highways, bridges, and large rivers, as alfo diforderly ale-houfes, bawdy-houfes, gaming-houfes, ftages for rope-dancers, &c. are held to be common nufances.—A private nufance is, when only one perfon or family is annoyed by the doing of any thing; as where a perfon ftops up the light of another's houfe, or builds in fuch a manner that the rain falls from his houfe upon his neighbour's.

NUT, among botanifts, denotes a PERICARPIUM of an extraordinary hardnefs, inclofing a kernel or feed.

NUTATION, in aftronomy, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former pofition.

NUT-HATCH, in ornithology. See SITTA.

NUTMEG, the kernel of a large fruit, not unlike the peach.

The nutmeg, as we receive it, is of a roundifh or oval figure, of a tolerably compact and firm texture, but eafily cut with a knife, and falling to pieces on a fmart blow. Its furface is not fmooth, but furrowed with a number of wrinkles, running in various directions, though principally longitudinally. It is of a greyifh-brown colour on the outfide, and of a beautiful variegated hue within, being marbled with brown and yellow variegations, running in perfect irregularity through its whole fubftance. It is very unctuous and fatty to the touch, when powdered; and is of an extremely agreeable fmell, and of an aromatic tafte.

There are two kinds of nutmeg in the fhops; the one called by authors the *male*, and the other the *female*. The female is the kind in common ufe, and is of the fhape of an olive: the male is long and cylindric, and has lefs of the fine aromatic flavour than the other; fo that it is much lefs efteemed, and people who trade largely in nutmegs will feldom buy it. The *longer male nutmeg*, as we term it, is called by the Dutch the *wild nutmeg*. It is always diftinguifhable from the others, as well by its want of fragrancy, as by its fhape: it is very fubject to be worm-eaten; and is ftrictly forbid, by the Dutch, to be packed up among the other, becaufe it will give occafion to their being worm-eaten too, by the infects getting from it into them, and breeding in all parts of the parcel.

The largeft, heavieft, and moft unctuous of the nutmegs are to be chofen, fuch as are of the fhape of

an olive, and of the moſt fragrant ſmell. The Dutch import them from the Eaſt-Indies.

The tree which produces the nutmeg grows only in the Banda iſlands. It has a pithy wood, an aſh-coloured bark, and flexible branches. The leaves are produced in pairs upon one ſingle ſtem; and, when bruiſed, emit an agreeable odour. The fruit ſucceeds the flowers, which reſemble thoſe of the cherry-tree. It is of the ſize of an egg, and of the colour of an apricot. The outer rind is very thick, and reſembles that of our nuts as they hang upon the tree, opening in the ſame manner when ripe, and diſcovering the nutmeg covered with its mace. It is then time to gather it, to prevent the mace or flower of the nutmeg from growing dry, and the nutmeg from loſing that oil which preſerves it, and in which its excellence conſiſts. Thoſe that are gathered before they are perfectly ripe, are preſerved in vinegar or ſugar, and admired only in Aſia.

This fruit requires nine months to bring it to perfection. After it is gathered, the outer rind is ſtripped off, and the mace ſeparated from it, and laid in the ſun to dry. The nuts require more preparation.— They are ſpread upon hurdles, and dried for ſix weeks by a ſlow fire, in ſheds erected for that purpoſe. They are then ſeparated from the ſhell, and thrown into lime-water, as a neceſſary preſervative againſt worms.

Nutmeg is greatly uſed in our foods, and is of excellent virtue as a medicine; it is a good ſtomachic, promotes digeſtion, and ſtrengthens the ſtomach. It alſo ſtops vomiting; is an excellent remedy in flatuſes; and is happily joined with rhubarb, and other medicines, in diarrhœas. It is obſerved to have a ſoporific virtue, and to exert it too ſtrongly if taken in immoderate quantities. It has a conſiderable degree of aſtringency; and given, after toaſting before the fire till thoroughly dry and crumbly, it has been ſometimes known alone to cure diarrhœas.

NUTRITION, in the animal-œconomy, is the repairing the continual loſs which the different parts of the body undergo. The motion of the parts of the body, the friction of theſe parts with each other, and eſpecially the action of the air, would deſtroy the body entirely, if the loſs was not repaired by a proper diet, containing nutritive juices; which being digeſted in the ſtomach, and afterwards converted into chyle, mix with the blood, and are diſtributed through the whole body for its nutrition.

In young perſons, the nutritive juices not only ſerve to repair the parts that are damaged, but alſo to increaſe them, which is called *growth*.

In grown perſons, the cuticle is every-where conſtantly deſquamating, and again renewing: and in the ſame manner the parts rubbed off, or otherwiſe ſeparated from the fleſhy parts of the body, are ſoon ſupplied with new fleſh; a wound heals, and an emaciated perſon grows plump and fat.

Buffon, in order to account for nutrition, ſuppoſes the body of an animal or vegetable to be a kind of mould, in which the matter neceſſary to its nutrition is modelled and aſſimilated to the whole. But (continues he) of what nature is this matter which an animal or vegetable aſſimilates to its own ſubſtance? What power is it that communicates to this matter the activity and motion neceſſary to penetrate this mould? and, if ſuch a force exiſt, would it not be by a ſimilar force that the internal mould itſelf might be reproduced?

As to the firſt queſtion, he ſuppoſes that there exiſts in nature an infinite number of living organical parts, and that all organized bodies conſiſt of ſuch organical parts; that their production coſts nature nothing, ſince their exiſtence is conſtant and invariable; ſo that the matter which the animal or vegetable aſſimilates to its ſubſtance, is an organical matter, of the ſame nature with that of the animal or vegetable, which conſequently may augment its volume without changing its form or altering the quality of the ſubſtance in the mould.

As to the ſecond queſtion: There exiſt (ſays he) in nature certain powers, as that of gravity, that have no affinity with the external qualities of the body, but act upon the moſt intimate parts, and penetrate them throughout, and which can never fall under the obſervation of our ſenſes.

And, as to the third queſtion, he anſwers, that the internal mould itſelf is reproduced, not only by a ſimilar power, but it is plain that it is the very ſame power that cauſes the unfolding and reproduction thereof: for it is ſufficient (proceeds he), that in an organized body that unfolds itſelf, there be ſome part ſimilar to the whole, in order that this part may one day become itſelf an organized body, altogether like that of which it is actually a part.

NUX PISTACHIA. See PISTACHIA.

NUX *Vomica*, a flat, compreſſed, round fruit, about the breadth of a ſhilling, brought from the Eaſt Indies. It is found to be a certain poiſon for dogs, cats, &c. and it is not to be doubted that it would alſo prove fatal to mankind. Its ſurface is not much corrugated; and its texture is firm like horn, and of a pale greyiſh-brown colour.

NYCHTHEMERON, the natural day, or day and night, which together make 24 hours.

NYCTALOPIA. See MEDICINE, n° 456.

NYCTANTHES, ARABIAN JASMINE; a genus of the monogynia order, belonging to the diandria claſs of plants. There are five ſpecies; the moſt remarkable of which are, 1. The arbor triſtis, or ſorrowful tree. This tree, or ſhrub, the *pariatacu* of the Bramins, grows naturally in ſandy places in India, particularly in the iſlands of Ceylon and Java, where it is produced in great abundance, and attains the height of 18 or 20 feet. It riſes with a four-cornered ſtem, bearing leaves that are oval, and taper to a point. They ſtand oppoſite, on ſhort foot-ſtalks; are of a ſhining browniſh-green on the upper-ſide, a more vivid green on the under, and of a taſte that is aſtringent and ſomewhat bitter. From the middle-rib, on the under-ſurface of the leaves, proceed on both ſides a number of coſtulæ, or ſmaller ribs, which run nearly to the margin, and mark the ſurface with the impreſſion of their arched furrows. The flowers, which are white, and highly odoriferous, having a ſweet delectable ſmell emulating the beſt honey, conſiſt of one petal deeply divided into eight parts, which are narrower towards the ſtalk, and dilated towards the ſummit. They ſtand upon foot-ſtalks, which emerge from the origin of the leaves; are rigid, obliquely

raifed towards the top, grow oppofite in pairs, and are divided into three fhort leffer branches, which each fupports five flowers placed clofe together, without partial foot-ftalks. The fruit is dry, capfular, membranaceous, and compreffed.

It is generally afferted of this plant, that the flowers open in the evening, and fall off the fucceeding day. Fabricius and Paludanus, however, reftrict the affertion, by affirming, from actual obfervation, that this effect is found to take place only in fuch flowers as are immediately under the influence of the folar rays. Grimmius remarks in his *Laboratorium Ceylonicum*, that the flowers of this tree afford a fragrant water, which is cordial, refrefhing, and frequently employed with fuccefs in inflammations of the eyes. The tube of the flower, when dried, has the fmell of faffron; and, being pounded and mixed with fanders-wood, is ufed by the natives of the Malabar coaft for imparting a grateful fragrancy to their bodies, which they rub or anoint with the mixture.

2. The fambac, noted, like the other fpecies, for the fragrancy of its flowers, is a native likewife of India; and is cultivated in our ftoves, where it generally rifes with a twining ftem, to the height of 18 or 20 feet. The leaves are oppofite, fimple, and entire; but in different parts of the plant affume different forms: the lower leaves being heart-fhaped and blunt; the upper, oval and fharp. The flowers are white, inexpreffibly fragrant, and generally appear with us in the warm fummer-months. Strong loam is its proper foil. There is a variety of this fpecies with a double flower, which is much larger and more fragrant than the former.

NYCTICORAX, in ornithology, the night-raven; a fpecies of Ardea.

NYLAND, a province of Finland in Sweden, lying on the gulf of Finland, to the weft of the province of Carelia.

NYMPH, in mythology, an appellation given to certain inferior goddeffes, inhabiting the mountains, wood, waters, &c. faid to be the daughters of Oceanus and Tethys. All the univerfe was reprefented as full of thefe nymphs, who are diftinguifhed into feveral ranks or claffes. The general divifion of them is into celeftial and terreftrial; the former of which were called *uraniæ*, and were fuppofed to be intelligences that governed the heavenly bodies or fpheres. The terreftrial nymphs, called *epigeiæ*, prefided over the feveral parts of the inferior world; and were divided into thofe of the water, and thofe of the earth. The nymphs of the water were the *oceanitides*, or nymphs of the ocean; the *nereids*, the nymphs of the fea; the *naiads* and *ephydriades*, the nymphs of the fountains; and the *limniades*, or nymphs of the lakes. The nymphs of the earth were the *oreades*, or nymphs of the mountains; the *napææ*, nymphs of the meadows; and the *dryads* and *hamadryads*, who were nymphs of the forefts and groves. Befides thefe, we meet with nymphs who took their names from particular countries, rivers, &c. as the *cithæroniades*, fo called from mount Cithæron in Bœotia; the *dodonides*, from Dodona; *tiberiades*, from the Tiber, &c.—Goats were fometimes facrificed to the nymphs; but their conftant offerings were milk, oil, honey, and wine.

Nymph, among naturalifts, that ftate of winged-infects between their living in the form of a worm, and their appearing in the winged or moft perfect ftate.

The eggs of infects are firft hatched into a kind of worms, or maggots; which afterwards pafs into the nymph-ftate, furrounded with fhells or cafes of their own fkins: fo that, in reality, thefe nymphs are only the embryo infects, wrapped up in this covering; from whence they at laft get loofe, though not without great difficulty.

During this nymph-ftate the creature lofes its motion. Swammerdam calls it *nympha aurelia*, or fimply *aurelia;* and others give it the name of *chryfalis*, a term of the like import. See the article Chrysalis.

Nymphæ, in anatomy, two membranaceous parts, fituated on each fide the rima. They are of a red colour, and cavernous ftructure, fomewhat refembling the wattles under a cock's throat. They are fometimes fmaller, fometimes larger; and are continuous to the præputium of the clitoris, and joined to the interior fide of the labia.

NYMPHÆA, the water-lily; a genus of the monogynia order, belonging to the polyandria clafs of plants. There are four fpecies; of which the moft remarkable are, 1, 2. The lutea and alba, or yellow and white water-lilies; both of which are natives of Britain, growing in lakes and ditches. Linnæus tells us, that fwine are fond of the leaves and roots of the former; and that the fmoke of it will drive away crickets and blattæ, or cock-roaches, out of houfes.—The root of the fecond has an aftringent and bitter tafte, like thofe of moft aquatic plants that run deep into the mud. The Highlanders make a dye with it of a dark cheftnut colour. 3. In the Eaft and Weft Indies grows a fpecies of this plant, named *nelumbo* by the inhabitants of Ceylon. The leaves which reft upon the furface of the water, are fmooth, undivided, perfectly round, thick, target-fhaped, and about one foot and a half in diameter. The footftalk of the leaves is prickly; and inferted, not into their bafe, or margin, as in moft plants, but in the centre of the lower difk or furface. From this centre, upon the upper furface, iffue, like rays, a great number of large ribs, or nerves, which towards the circumference are divided and fubdivided into a fmall number of very minute parts. The flowers are large, flefh-coloured, and confift of numerous petals, difpofed, as in the other fpecies of water-lily, in two or more rows. The feed-veffel is fhaped like a top, being broad and circular above, narrow and almoft pointed below. It is divided into feveral diftinct cells, which form fo many large round holes upon the furface of the fruit; each containing a fingle feed.—With the flower of this plant, which is facred among the heathens, they adorn the altars of their temples: they paint their gods fitting upon it; and make ufe of fuch pictures to animate the minds of the pious on their death-bed, and to raife their affections to heaven. The ftalks, which are ufed as a pot-herb, are of a wonderful length. The root is very long, extends itfelf tranfverfely, is of the thicknefs of a man's arm, jointed and fibrous, with long intervals betwixt the joints. The fibres furround the joints in verticilli, or whirls.

NYMPHEUM, in antiquity, a public hall magnificently decorated, for entertainment, &c. and where thofe who wanted convenience at home held their marriage-

riage-feafts, whence the name.

NYON, a confiderable town of Switzerland, in the canton of Bern, and capital of a bailiwick of the fame name, with a caftle. There are a great many Roman infcriptions here; and it is a trading place, feated in a good country, near the lake of Geneva. E. Long. 5. 10. N. Lat. 46. 24.

NYSLOT, a ftrong town of Ruffia, in Livonia, with a caftle; feated on the river Narva, among large marfhes. E. Long. 26. 55. N. Lat. 58. 46.

NYSSA, a genus of the order of dioecia, belonging to the polygamia clafs of plants. There is but one fpecies, *viz.* The aquatica, or water-tupelo-tree. This has a large trunk, efpecially near the ground, and grows very tall. The leaves are broad, and irregularly notched. The flowers come out from the fides of the branches, on footftalks of three inches long, and are of a greenifh colour. The grain of the wood is foft and fpongy; but the roots much more fo, approaching near to the confiftence of cork; and are ufed for the purpofes of cork in Carolina, where thefe trees are natives. They grow in wet places, and ufually in the fhallow parts of rivers.

O

O, The 14th letter and fourth vowel of our alphabet; pronounced as in the words *nofe*, *rofe*, &c.

The found of this letter is often fo foft as to require it double, and that chiefly in the middle of words; as *goofe*, *reproof*, &c. And in fome words this *oo* is pronounced like *u* fhort, as in *flood*, *blood*, &c.

As a numeral, O is fometimes is ufed for 11; and with a dafh over it thus, $\bar{\text{O}}$, for 11,000.

In the notes of the ancients, O. CON. is read *opus conductum;* O. C. Q. *opera confilioque;* O. D. M. *operæ, donum, munus;* and O. LO. *opus locatum.*

In mufic, the O, or rather a circle, or double CO, is a note of time, called by us a *femi-breve;* and by the Italians, *circolo.* The O is alfo ufed as a mark of triple time, as being the moft perfect of all figures. See TRIPLE.

OAK, in botany. See QUERCUS.

OAK-*Leaves.* The ufes of oak-bark in tanning, and in hot-beds, is generally known. For the latter of thefe purpofes, however, oak-leaves are now found to anfwer equally well, or rather better. In the notes to Dr Hunter's edition to Evelyn's Treatife on Foreft-trees, we find the following directions for their ufe by W. Speechly. The leaves are to be raked up as foon as poffible after they fall from the trees. When raked into heaps, they fhould immediately be carried into fome place near the hot-houfes, where they may lie to couch. Mr Speechly fays it was his cuftom to fence them round with charcoal hurdles, or any thing elfe, to keep them from being blown about the garden in windy weather. In this place they tread them well, and water them in cafe they happen to have been brought in dry. The heap is made fix or feven feet thick, and covered over with old mats, or any thing elfe, to prevent the upper leaves from being blown away. In a few days the heap will come to a ftrong heat. For the firft year or two in which he ufed thefe leaves, our author did not continue them in the heap longer than ten days or a fortnight: but by this method of management they fettled fo much when brought to the hot-houfe, that a fupply was very foon required; and he afterwards found, that it was proper to let them remain five or fix weeks in the heaps before they are brought to the hot-houfe. In getting them into the pine-pits, if they appear dry, they are to be watered, and again trodden down exceedingly well, in layers, till the pits are quite full. The whole is then covered with tan-bark, to the thicknefs of two inches, and well trodden down, till the furface becomes fmooth and even. On this the pine-pots are to be placed in the manner they are to ftand, beginning with the middle row firft, and filling up the fpaces between the pots with tan. In this manner we are to proceed to the next row, till the whole be finifhed; and this operation is performed in the fame manner as when tan only is ufed. The leaves require no further trouble through the whole feafon; as they will retain a conftant and regular heat for 12 months without ftirring or turning; and our author informs us, that if he may judge from their appearance when taken out, (being always entire and perfect), it is probable they would continue their heat through a fecond year; but, as an annual fupply of leaves is eafily obtained, the experiment is hardly worth making. After this, the pines will have no occafion to be moved, but at ftated times of their management, *viz.* at the fhifting them in their pots, &c. when at each time a little frefh tan fhould be added to make up the deficiency arifing from the fettling of the beds; but this will be inconfiderable, as the leaves do not fettle much after their long couching. During the firft two years of our author's practice he did not ufe any tan, but plunged the pine-pots into the leaves, and juft covered the furface of the beds, when finifhed, with a little faw-duft, to give it a neatnefs. This method, however, was attended with one inconvenience; for by the caking of the leaves they fhrunk from the fides of the pots, whereby they became expofed to the air, and at the fame time the heat of the beds was permitted to efcape.

"Many powerful reafons, fays Mr Speechly, may be given why oak-leaves are preferable to tanner's-bark.

"1. They always heat regularly; for during the whole time that I have ufed them, which is near feven years, I never once knew of their heating with violence; and this is fo frequently the cafe with tan, that I affirm, and indeed it is well known to every perfon converfant in the management of the hot-houfe, that pines fuffer more from this one circumftance, than all the other accidents put together, infects excepted.

When this accident happens near the time of their fruiting, the effect is soon seen in the fruit, which is exceedingly small and ill-shaped. Sometimes there will be little or no fruit at all; therefore gardeners who make use of tan only for their pines, should be most particularly careful to avoid an over-heat at that critical juncture,—the time of shewing the fruit.

"2. The heat of oak-leaves is constant; whereas tanner's bark generally turns cold in a very short time after its furious heat is gone off. This obliges the gardener to give it frequent turnings in order to promote its heating. These frequent turnings, not to mention the expence, are attended with the worst consequences; for by the continual moving of the pots backwards and forwards, the pines are exposed to the extremes of heat and cold, whereby their growth is considerably retarded; whereas, when leaves are used, the pines will have no occasion to be moved but at the times of potting, &c. The pines have one peculiar advantage in this undisturbed situation; their roots grow through the bottoms of the pots, and mat among the leaves in a surprising manner. From the vigour of the plants when in this situation, it is highly probable that the leaves, even in this state, afford them an uncommon and agreeable nourishment.

"3. There is a saving in point of expence; which is no inconsiderable object in places where tan cannot be had but from a great distance.

"4. The last ground of preference is, that decayed leaves make good manure; whereas rotten tan is experimentally found to be of no value. I have often tried it both on sand and clay, and on wet and dry land; and never could discover, in any of my experiments, that it deserved the name of a manure; whereas decayed leaves are the richest, and of all others the most proper manure for a garden. Leaves mixed with dung make excellent hot-beds; and I find that beds compounded in this manner, preserve their heat much longer than when made entirely with dung; and in both cases, the application of leaves will be a considerable saving of dung, which is a circumstance on many accounts agreeable."

OAK *Saw-dust* is now found to answer the purposes of tanning as well, at least, as the bark. See TANNING.

OAK *of Jerusalem*. See CHENOPODIUM.

OAKAM, old ropes untwisted and pulled out into loose hemp, in order to be used in caulking the seams, tree-nails, and bends of a ship, for stopping or preventing leaks.

OAKHAMPTON, a town of Devonshire, which sends two members to parliament; situated in E. Long. 1. 47. N. Lat. 45. 4.

OAR, a long piece of timber, flat at one end, and round or square at the other, and which being applied to the side of a floating-vessel, serves to make it advance upon the water.

That part of the oar which is out of the vessel, and which enters into the water, is called the *blade*, or *wash*, *plat*; and that which is within-board is termed the *loom*, whose extremity being small enough to be grasped by the rowers, or persons managing the oars, is called the *handle*.

To push the boat or vessel forwards by means of this instrument, the rowers turn their backs forward, and, dipping the blade of the oar in the water, pull the handle forward so that the blade at the same time may move aft in the water: but since the blade cannot be so moved, without striking the water, this impulsion is the same, as if the water were to strike the blade from the stern towards the head: the vessel is therefore necessarily moved according to this direction. Hence it follows, that she will advance with the greater rapidity, by as much as the oar strikes the water more forcibly. Thus it is evident, that an oar acts upon the side of a boat or vessel like a lever of the second class, whose fulcrum is the station upon which the oar rests on the boat's gunnel. In large vessels, this station is usually called the *row-port*; but in lights and boats it is always termed the *row lock*.

OAT, in botany. See AVENA.

OATH, is a solemn affirmation, in which the persons sworn invoke the Almighty to witness that their testimony is true; renouncing all claim to his mercy, and calling for vengeance, if it be false.

Coronation-OATH. See KING.

OBADIAH, or the *Prophecy of* OBADIAH, a canonical book of the Old Testament, which is contained in one single chapter; and is partly an invective against the cruelty of the Ebonites, who mocked and derided the children of Israel, as they passed into captivity, and with other enemies, their confederates, invaded and oppressed those strangers, and divided the spoil amongst themselves; and partly a prediction of the deliverance of Israel, and of the victory and triumph of the whole church over her enemies.

OBELISK, in architecture, a truncated, quadrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphics.

Obelisks appear to be of very great antiquity, and to be first raised to transmit to posterity precepts of philosophy, which were cut in hieroglyphical characters: afterwards they were used to immortalize the great actions of heroes, and the memory of persons beloved. The first obelisk mentioned in history was that of Ramases king of Egypt, in the time of the Trojan war, which was 40 cubits high. Phius, another king of Egypt, raised one of 45 cubits: and Ptolemy Philadelphus, another of 88 cubits, in memory of Arsinoë. Augustus erected one at Rome in the Campus Martius, which served to mark the hours on an horizontal dial, drawn on the pavement. They were called by the Egyptian priests the *fingers of the sun*, because they were made in Egypt also to serve as styles or gnomons to mark the hours on the ground. The Arabs still call them *Pharaoh's needles*: whence the Italians call them *aguglia*, and the French *aiguilles*.

OBJECT, in philosophy, something apprehended or presented to the mind by sensation or imagination. See METAPHYSICS.

OBJECT-*Glass of a Telescope*, or *Microscope*, the glass placed at the end of the tube which is next the object. See OPTICS.

OBJECTION, something urged to overthrow a position, or a difficulty raised against an allegation or proposition of a person we are disputing withal.

OBJECTIVE, is used in the schools, in speaking of a thing which exists no otherwise than as an object known.

A. Bell Sculp.t

known. The exiftence of fuch a thing is faid to be objective.

OBIT, (Lat.) fignifies a funeral folemnity, or office for the dead, moft commonly performed when the corpfe lies in the church uninterred: Alfo the anniverfary office, (2 Cro. 51 Dyer 313). The anniverfary of any perfon's death was called the *obit;* and to obferve fuch day with prayers and alms, or other commemoration, was the keeping of the obit. In religious houfes they had a regifter, wherein they entered the obits or obitual days of their founders and benefactors; which was thence termed the *obituary*. The tenure of obit or chantry lands is taken away and extinct by 1 Edw. VI. c. 14. and 15 Car. II. c. 9.

OBLATI, in church-hiftory, were fecular perfons, who devoted themfelves and their eftates to fome monaftery, into which they were admitted as a kind of lay-brothers. The form of their admiffion, was putting the bell-ropes of the church round their necks, as a mark of fervitude. They wore a religious habit, but different from that of the monks.

OBLIGATION, in general, denotes any act whereby a perfon becomes bound to another to do fomething; as to pay a fum of money, be furety, or the like.

Obligations are of three kinds, *viz.* natural, civil, and mixed. Natural obligations are entirely founded on natural equity; civil obligation, on civil authority alone, without any foundation in natural equity; and mixed obligations are thofe which, being founded on natural equity, are farther enforced by a civil authority.

In a legal fenfe, obligation fignifies a bond, wherein is contained a penalty, with a condition annexed for the payment of money, &c. The difference between it and a bill is, that the latter is generally without a penalty or condition, though it may be made obligatory: and obligations are fometimes by matter of record, as ftatutes and recognizances. See the article Bond.

Moral Obligation. See Morals, n° 36—40.

OBLIQUE, in geometry, fomething aflant, or that deviates from the perpendicular. Thus an oblique angle, is either an acute or obtufe one, *i. e.* any angle except a right one.

Oblique *Cafes*, in grammar, are all the cafes except the nominative. See Case.

Oblique *Line*, that which, falling on another line, makes oblique angles with it, *viz.* one acute, and the other obtufe.

Oblique *Planes*, in dialling, are thofe which decline from the zenith, or incline towards the horizon. See Dial.

Oblique *Sailing*, in navigation, is when a fhip fails upon fome rhumb between the four cardinal points, making an oblique angle with the meridian; in which cafe, fhe continually changes both latitude and longitude. See Navigation, §. 6.

OBLIQUUS, in anatomy, a name given to feveral mufcles, particularly in the head, eyes, and abdomen. See Anatomy, *Table of the Mufcles*.

OBLONG, in general, denotes a figure that is longer than broad: fuch is a parallellogram, ellipfis, &c.

OBOLUS, an ancient filver money of Athens, the

fixth part of a drachma; worth fomewhat more than penny-farthing Sterling.—The word comes from the Greek ὀϐολὸς, of ὀϐελὸς, "fpit, or broach;" either becaufe it bore fuch an impreffion; or becaufe, according to Euftachius, it was in form thereof. But thofe now in the cabinets of the antiquaries are round.

Obolus, in medicine, is ufed for a weight of ten grains, or half a fcruple.

OBRECHT (Ulric), a learned German, born of a noble family at Strafburg in 1646, where he filled the chairs of civil law and hiftory with great diftinction. He was of the Proteftant religion; but when Lewis XIV. made himfelf mafter of Strafburg, and went there with his court, he was prevailed on to change; and accordingly abjured in 1684, and put his inftrument into the hands of Boffuet bifhop of Meaux. The next year the king nominated him to prefide in his name in the fenate of Strafburg, with the title of prætor royal, in imitation of the ancient Romans; from which time Mr Obrecht applied himfelf entirely to public affiairs. He was the editor, tranflator, and writer, of feveral learned works; and died in 1701.

OBREPTITIOUS, an appellation given to letters patent, or other inftruments, obtained of a fuperior by furprife, or by concealing from him the truth.

OBSCURE, fomething that is dark and reflects little light, or that is not clear and intelligible.

OBSECRATION, in rhetoric, a figure whereby the orator implores the affiftance of God or man.

OBSEQUENS (Julius), a Latin writer, conjectured to have lived before the emperor Honorius's reign. He made a collection of the prodigies which Livy related in his hiftory. There are feveral editions of thofe remains. Lycofthenes endeavoured to fupply what was wanting in the original.

OBSEQUIES, the fame with funeral folemnities. See Funeral.

OBSERVATION, among navigators, fignifies the taking the fun's or the ftars meridian altitude, in order thereby to find the latitude.

OBSERVATORY, a place deftined for obferving the heavenly bodies; being generally a building erected on fome eminence, covered with a terrace for making aftronomical obfervations.

The more celebrated obfervatories are, 1. The Greenwich obfervatory, built in 1676, by order of Charles II. at the folicitation of Sir Jonas Moore and Sir Chriftopher Wren; and furnifhed with the moft accurate inftruments, particularly a noble fextant of feven feet radius, with telefcopic fights.

2. The Paris obfervatory, built by the order of Louis XIV. in the Fauxbourg, St Jaques.

It is a very fingular, but withal a very magnificent building, the defign of Monfieur Perault: it is eighty feet high; and at top is a terrace.

The difference in longitude between this and the Greenwich obfervatory is 2° 20′ weft.

In it is a cave, or cellar, of 170 feet defcent, for experiments that are to be made far from the fun, &c. particularly fuch as relate to congelations, refrigerations, indurations, confervations, &c.

3. Tycho Brahe's obfervatory, which was in the little ifland Ween, or Scarlet Ifland, between the coafts of Schonen and Zealand, in the Baltic. It was erected and furnifhed with inftruments at his own ex-

pence, and called by him *Uraniburg*. Here he fpent twenty years in obferving the ftars; the refult is his catalogue.

4. Pekin obfervatory. Father Le Compte defcribes a very magnificent obfervatory, erected and furnifhed by the late emperor of China, in his capital, at the interceffion of fome Jefuit miffionaries, principally Father Verbeift, whom he made his chief obferver.—The inftruments are exceedingly large; but the divifion lefs accurate, and the contrivance in fome refpects lefs commodious, than that of the Europeans. The chief are, An armillary zodiacal fphere of fix feet diameter; an equinoctial fphere of fix feet diameter; an azimuthal horizon of fix feet diameter; a large quadrant fix feet radius; a fextant eight feet radius; and a celeftial globe fix feet diameter.

5. Bramins obfervatory at Benares. Of this Sir Robert Barker gives the following account, Phil. Tranf. Vol. LXVII. p. 598. " Benares in the Eaft Indies, one of the principal feminaries of the Bramins or priefts of the original Gentoos of Hindoftan, continues ftill to be the place of refort of that fect of people; and there are many public charities, hofpitals, and pagodas, where fome thoufands of them now refide. Having frequently heard that the ancient Bramins had a knowledge of aftronomy, and being confirmed in this by their information of an approaching eclipfe both of the fun and moon, I made inquiry, when at that place in the year 1772, among the principal Bramins, to endeavour to get fome information relative to the manner in which they were acquanted of an approaching eclipfe. The moft intelligent that I could meet with, however, gave me but little fatisfaction. I was told, that thefe matters were confined to a few, who were in poffeffion of certain books and records; fome containing the myfteries of their religion; and others the tables of aftronomical obfervations, written in the Skanfkirrit language, which few underftood but themfelves: that they would take me to a place which had been conftructed for the purpofe of making fuch obfervations as I was inquiring after, and from whence they fuppofed the learned Bramins made theirs. I was then conducted to an ancient building of ftone, the lower part of which, in its prefent fituation, was converted into a ftable for horfes, and a receptacle for lumber; but, by the number of court-yards and apartments, it appeared that it muft once have been an edifice for the ufe of fome public body of people. We entered this building, and went up a ftair-cafe to the top of a part of it, near to the river Ganges, that led to a large terrace, where, to my furprife and fatisfaction, I faw a number of inftruments yet remaining, in the greateft prefervation, ftupendoufly large, immoveable from the fpot, and built of ftone, fome of them being upwards of 20 feet in height; and, although they are faid to have been erected 200 years ago, the graduations and divifions on the feveral arcs appeared as well cut, and as accurately divided, as if they had been the performance of a modern artift. The execution in the conftruction of thefe inftruments exhibited a mathematical exactnefs in the fixing, bearing, fitting of the feveral parts, in the neceffary and fufficient fupports to the very large ftones that compofed them, and in the joining and faftening each into the other by means of lead and iron.

" The fituation of the two large quadrants of the inftrument marked A in the plate, whofe radius is nine feet two inches, by their being at right angles with a gnomon at twenty-five degrees elevation, are thrown into fuch an oblique fituation as to render them the moft difficult, not only to conftruct of fuch a magnitude, but to fecure in their pofition for fo long a period, and affords a ftriking inftance of the ability of the architect in their conftruction: for, by the fhadow of the gnomon thrown on the quadrants, they do not appear to have altered in the leaft from their original pofition; and fo true is the line of the gnomon, that, by applying the eye to a fmall iron ring of an inch diameter at one end, the fight is carried through three others of the fame dimenfion, to the extremity at the other end, diftant 38 feet 8 inches, without obftruction; fuch is the firmnefs and art with which this inftrument has been executed. This performance is the more wonderful and extraordinary when compared with the works of the artificers of Hindoftan at this day, who are not under the immediate direction of an European mechanic; but arts appear to have declined equally with fcience in the eaft.

Plate CCV.

" Lieutenant-colonel Archibald Campbell, at that time chief engineer in the Eaft India Company's fervice at Bengal, made a perfpective drawing of the whole of the apparatus that could be brought within his eye at one view; but I lament he could not reprefent fome very large quadrants, whofe radii were about twenty feet, they being on the fide from whence he took his drawing. Their defcription however is, that they are exact quarters of circles of different radii, the largeft of which I judged to be 20 feet, conftructed very exactly on the fides of ftone-walls built perpendicular, and fituated, I fuppofe, in the meridian of the place: a brafs pin is fixed at the centre or angle of the quadrant, from whence, the Bramin informed me, they ftretched a wire to the circumference when an obfervation was to be made; from which it occurred to me, the obferver muft have moved his eye up or down the circumference, by means of a ladder or fome fuch contrivance, to raife and lower himfelf, until he had difcovered the altitude of any of the heavenly bodies in their paffage over the meridian, fo expreffed on the arcs of thefe quadrants: thefe arcs were very exactly divided into nine large fections; each of which again into ten, making ninety leffer divifions or degrees; and thofe alfo into twenty, expreffing three minutes each, of about two-tenths of an inch afunder; fo that it is probable, they had fome method of dividing even thefe into more minute divifions at the time of obfervation.

" My time would only permit me to take down the particular dimenfions of the moft capital inftrument, or the greater equinoctial fun-dial, reprefented by figure A, which appears to be an inftrument to exprefs folar time by the fhadow of a gnomon upon two quadrants, one fituated to the eaft, and the other to the weft of it; and indeed the chief part of their inftruments at this place appear to be conftructed for the fame purpofe, except the quadrants, and a brafs inftrument that will be defcribed hereafter.

" Figure B is another inftrument for the purpofe of determining the exact hour of the day by the fhadow

dow of a gnomon, which ftands perpendicular to and in the centre of a flat circular ftone, fupported in an oblique fituation by means of four upright ftones and a crofs-piece ; fo that the fhadow of the gnomon, which is a perpendicular iron rod, is thrown upon the divifion of the circle defcribed on the face of the flat circular ftone.

"Figure C is a brafs circle, about two feet diameter, moving vertically upon two pivots between two ftone pillars, having an index or hand turning round horizontally on the centre of this circle, which is divided into 360 parts ; but there are no counter divifions on the index to fubdivide thofe on the circle. This inftrument appears to be made for taking the angle of a ftar at fetting or rifing, or for taking the azimuth or amplitude of the fun at rifing or fetting.

"The ufe of the inftrument, figure D, I was at a lofs to account for. It confifts of two circular walls; the outer of which is about forty feet diameter, and eight feet high ; the wall within about half that height, and appears intended for a place to ftand on to obferve the divifions on the upper circle of the outer wall, rather than for any other purpofe ; and yet both circles are divided into 360 degrees, each degree being fubdivided into twenty leffer divifions, the fame as the quadrants. There is a door-way to pafs into the inner circle, and a pillar in the centre, of the fame height with the lower circle, having a hole in it, being the centre of both circles, and feems to be a focket for an iron rod to be placed perpendicular into it. The divifions on thefe, as well as all the other inftruments, will bear a nice examination with a pair of compaffes.

"Figure E is a fmaller equinoctial fun-dial, conftructed upon the fame principle as the large one A.

"I cannot quit this fubject without obferving, that the Bramins, without the affiftance of optical glaffes, had neverthelefs an advantage unexperienced by the obfervers of the more northern climates. The ferenity and clearnefs of the atmofphere in the nighttime in the Eaft Indies, except at the feafons of changing the monfoons or periodical winds, is difficult to exprefs to thofe who have not feen it, becaufe we have nothing in comparifon to form our ideas upon : it is clear to perfection, a total quietude fubfifts, fcarcely a cloud to be feen, and the light of the heavens, by the numerous appearance of the ftars, affords a profpect both of wonder and contemplation.

"This obfervatory at Benares is faid to have been built by the order of the emperor Ackbar: for as this wife prince endeavoured to improve the arts, fo he wifhed alfo to recover the fciences of Hindoftan, and therefore directed that three fuch places fhould be erected ; one at Delhi, another at Agra, and the third at Benares."

Edinburgh OBSERVATORY. See EDINBURGH.

OBSIDIANUS LAPIS, in the natural hiftory of the ancients, the name of a ftone which they have alfo defcribed under the name of the *Chian marble*. It is a very fmooth and hard marble, extremely difficult to cut, but capable of a fine polifh ; and was ufed among the ancient Greeks for the purpofe of making reflecting mirrors. The later writers have fuppofed the name *obfidianus* to be derived from fomebody called *Obfidius*, who was the inventor of this ufe of it; but it feems only a falfe fpelling of the word *opfianus*, απο της οψεως, from feeing the images of things in it.

OBSIDIONALIS, an epithet applied by the Romans to a fort of crown. See the article CROWN.

OBSTETRICS, or the OBSTETRIC ART, the fame with MIDWIFERY.

OBSTRUCTION, in medicine, fuch an obturation of the veffels as prevents the circulation of the fluids, whether of the found and vital, or of the morbid and peccant kind, through them.

OBTURATOR, in anatomy. See ANATOMY, *Table of the Mufcles*.

OBTUSE, fignifies blunt, dull, &c. in oppofition to acute or fharp. Thus we fay, obtufe angle ; obtufe angled triangle, &c.

OBY, or OB, a river of the Ruffian empire in Afia, which rifes in the defart of Ifchinfka, and, running north, joins the Irtis near Tobolfk ; and, ftill keeping its name, continues its courfe north, and falls into a deep bay called *Obfkaya*, in about 63 degrees of latitude. The exact courfe of this river was unknown, till the country was furveyed by the Ruffians ; who have given us good maps of it and of all Siberia. The Oby forms the boundary between Europe and Afia, and its courfe is upwards of 2000 miles in length.

OCCIDENT, in geography, the weftward quarter of the horizon ; or that part of the horizon where the ecliptic, or the fun therein, defcends into the lower hemifphere; in contradiftinction to *orient*. Hence we ufe the word *occidental* for any thing belonging to the weft ; as occidental bezoar, occidental pearl, &c.

OCCIPITAL, in anatomy, a term applied to the parts of the occiput, or back part of the fkull.

OCCULT, fomething hidden, fecret, or invifible. The occult fciences are magic, necromancy, cabbala, &c.

OCCULT, in geometry, is ufed for a line that is fcarce perceivable, drawn with the point of the compaffes or a leaden pencil. Thefe lines are ufed in feveral operations, as the raifing of plans, defigns of building, pieces of perfpective, &c. They are to be effaced when the work is finifhed.

OCCULTATION, in aftronomy, the time a ftar or planet is hid from our fight, by the interpofition of the body of the moon or fome other planet.

OCCUPANCY, in law, is the taking poffeffion of thofe things which before belonged to nobody. This is the true ground and foundation of all PROPERTY, or of holding thofe things in feveralty, which by the law of nature, unqualified by that of fociety, were common to all mankind. But, when once it was agreed that every thing capable of ownerfhip fhould have an owner, natural reafon fuggefted, that he who could firft declare his intention of appropriating any thing to his own ufe, and, in confequence of fuch his intention, actually took it into poffeffion, fhould thereby gain the abfolute property of it; according to that rule of the law of nations, recognized by the laws of Rome, *quod nullius eft, id ratione naturali occupanti conceditur*. *Blackft. Comment.*

Occupancy. This right of occupancy, ſo far as it concerns real property, hath been confined by the laws of England within a very narrow compaſs; and was extended only to a ſingle inſtance; namely, where a man was tenant *pour autre vie*, or had an eſtate granted to himſelf only (without mentioning his heirs) for the life of another man, and died during the life of *ceſtuy que vie*, or him by whoſe life it was holden: in this caſe, he that could firſt enter on the land, might lawfully retain the poſſeſſion ſo long as *ceſtuy que vie* lived, by right of occupancy.

This ſeems to have been recurring to firſt principles, and calling in the law of nature to aſcertain the property of the land, when left without a legal owner, For it did not revert to the grantor; who had parted with all his intereſt, ſo long as *ceſtuy que vie* lived: it did not eſcheat to the lord of the fee; for all eſcheats muſt be of the abſolute entire fee, and not of any particular eſtate carved out of it; much leſs of ſo minute a remnant as this: it did not belong to the grantee; for he was dead: it did not deſcend to his heirs; for there were no words of inheritance in the grant: nor could it veſt in his executors; for no executors could ſucceed to a freehold. Belonging therefore to nobody, like the *hæreditas jacens* of the Romans, the law left it open to be ſeiſed and appropriated by the firſt perſon that could enter upon it, during the life of *ceſtuy que vie*, under the name of an occupant. But there was no right of occupancy allowed, where the king had the reverſion of the lands: for the reverſioner hath an equal right with any other man to enter upon the vacant poſſeſſion; and where the king's title and a ſubject's interfere, the king's ſhall always be preferred. Againſt the king therefore there could be no prior occupant, becauſe *nullum tempus occurrit regi.* And, even in the caſe of a ſubject, had the eſtate *pour autre vie* been granted to a man *and his heirs* during the life of *ceſtuy qui vie*, there the heir might, and ſtill may, enter and hold poſſeſſion, and is called in law a *ſpecial occupant;* as having a ſpecial excluſive right, by the terms of the original grant, to enter upon and occupy this *hæreditas jacens*, during the reſidue of the eſtate granted: though ſome have thought him ſo called with no very great propriety; and that ſuch eſtate is rather a deſcendible freehold. But the title of *common occupancy* is now reduced almoſt to nothing by two ſtatutes; the one, 29 Car. II. c. 3. which enacts, that where there is no ſpecial occupant, in whom the eſtate may veſt, the tenant *pour autre vie* may deviſe it by will, or it ſhall go to the executors and be aſſets in their hands for payment of debts: the other that of 14 Geo. II. c. 20. which enacts, that it ſhall veſt not only in the executors, but, in caſe the tenant dies inteſtate, in the adminiſtrators alſo; and go in courſe of a diſtribution like a chattel intereſt.

By theſe two ſtatutes the title of *common occupancy* is utterly extinct and aboliſhed: tho' that of *ſpecial occupancy*, by the heir at law, continues to this day; ſuch heir being held to ſucceed to the anceſtor's eſtate, not by deſcent, for then he muſt take an eſtate of inheritance, but as an occupant, ſpecially marked out and appointed by the original grant. The doctrine of common occupancy may, however, be uſefully remembered on the following account, amongſt others: That, as by the common law no occupancy could be of incorporeal hereditaments, as of rents, tithes, advowſons, commons, Occupancy. or the like, (becauſe, with reſpect to them, there could be no actual entry made, or corporal ſeiſin had; and therefore by the death of the grantee *pour autre vie* a grant of ſuch hereditaments was entirely determined): ſo now, it is apprehended, notwithſtanding thoſe ſtatutes, ſuch grant would be determined likewiſe; and the hereditaments could not be deviſeable, nor veſt in the executors, nor go in a courſe of diſtribution. For the ſtatutes muſt not be conſtrued ſo as to create any new eſtate, or to keep that alive which by the common law was determined, and thereby to defeat the grantor's reverſion; but merely to diſpoſe of an intereſt in being, to which by law there was no owner, and which therefore was left open to the firſt occupant. When there is a reſidue left, the ſtatutes give it to the executors, &c. inſtead of the firſt occupant; but they will not create a reſidue, on purpoſe to give it to the executors. They only mean to provide an appointed inſtead of a caſual, a certain inſtead of an uncertain, owner, of lands which before were nobody's; and thereby to ſupply this *caſus omiſſus*, and render the diſpoſition of the law in all reſpects entirely uniform: this being the only inſtance wherein a title to a real eſtate could ever be acquired by occupancy.

For there can be no other caſe deviſed, wherein there is not ſome owner of the land appointed by the law. In the caſe of a ſole corporation, as a parſon of a church, when he dies or reſigns, though there be no *actual* owner of the land till a ſucceſſor be appointed, yet there is a *legal, potential* ownerſhip, ſubſiſting in contemplation of law; and when the ſucceſſor is appointed, his appointment ſhall have a retroſpect and relation backwards, ſo as to entitle him to all the profits from the inſtant that the vacancy commenced. And, in all other inſtances, when the tenant dies inteſtate, and no other owner of the lands is to be found in the common courſe of deſcents, there the law veſts an ownerſhip in the king, or in the ſubordinate lord of the fee, by eſcheat.

So alſo, in ſome caſes, where the laws of other nations give a right by occupancy, as in lands newly created, by the riſing of an iſland in a river, or by the alluvion or dereliction of the ſea; in theſe inſtances, the law of England aſſigns them an immediate owner. For Bracton tells us, that if an iſland ariſe in the *middle* of a *river*, it belongs in common to thoſe who have lands on each ſide thereof; but if it be nearer to one bank than the other, it belongs only to him who is proprietor of the neareſt ſhore: which is agreeable to, and probably copied from, the civil law. Yet this ſeems only to be reaſonable, where the ſoil of the river is equally divided between the owners of the oppoſite ſhores: for if the whole ſoil is the freehold of any one man, as it muſt be whenever a ſeveral fiſhery is claimed, there it ſeems juſt (and ſo is the uſual practice) that the iſlets, or little iſlands, ariſing in any part of the river, ſhall be the property of him who owneth the piſcary and the ſoil. However, in caſe a new iſland riſe in the *ſea*, though the civil law gives it to the firſt occupant, yet our's gives it to the king. And as to lands gained from the ſea; either by *alluvion*, by the waſhing up of ſand and earth, ſo as in time to make *terra firma;* or by *dereliction*, as when the ſea ſhrinks back below the uſual water-mark; in theſe

these cases the law is held to be, that if this gain be by little and little, by small and imperceptible degrees, it shall go to the owner of the land adjoining. For *de minimis non curat lex:* and, besides, these owners being often losers by the breaking in of the sea, or at charges to keep it out, this possible gain is therefore a reciprocal consideration for such possible charge or loss. But if the alluvion or dereliction be sudden and considerable, in this case it belongs to the king: for, as the king is lord of the sea, and so owner of the soil while it is covered with water, it is but reasonable he should have the soil when the water has left it dry. So that the quantity of ground gained, and the time during which it is gained, are what make it either the king's or the subject's property. In the same manner, if a river, running between two lordships, by degrees gains upon the one, and thereby leaves the other dry; the owner who loses his ground thus imperceptibly has no remedy: but if the course of the river be changed by a sudden and violent flood, or other hasty means, and thereby a man loses his ground, he shall have what the river has left in any other place, as a recompence for this sudden loss. And this law of alluvions and derelictions, with regard to *rivers*, is nearly the same in the imperial law; from whence indeed those our determinations seem to have been drawn and adopted: but we ourselves, as islanders, have applied them to *marine* increases; and have given our sovereign the prerogative he enjoys, as well upon the particular reasons before-mentioned, as upon this other general ground of prerogative, which was formerly remarked, that whatever hath no other owner is vested by law in the king. See PREROGATIVE.

OCCUPANT, in law, the person that first seizes or gets possession of a thing.

OCCUPATION, in a legal sense, is taken for use or tenure; as in deeds it is frequently said, that such lands are, or were lately, in the tenure of occupation of such a person.—It is likewise used for a trade or mystery.

OCCUPIERS *of* WALLING, a term used in the salt-works for the persons who are the sworn officers that allot in particular places what quantity of salt is to be made, that the markets may not be overstocked, and see that all is carried fairly and equally between the lord and the tenant.

OCEAN, in geography, that vast collection of salt and navigable waters, in which the two continents, the first including Europe, Asia, and Africa, and the last America, are inclosed like islands.

The ocean is distinguished into three grand divisions. 1. The Atlantic ocean, which divides Europe and Africa from America, which is generally about 3000 miles wide. 2. The Pacific ocean, or South-sea, which divides America from Asia, and is generally about 10,000 miles over. And, 3. The Indian ocean, which separates the East Indies from Africa; which is 3000 miles over. The other seas, which are called *oceans*, are only parts or branches of these, and usually receive their names from the countries they border upon.

For the saltness, tides, &c. of the ocean, see the articles SEA, TIDES, &c.

OCEANUS, in Pagan mythology, the son of Cælus and Terra, the husband of Thetis, and the father of the Rivers and Fountains. The ancients called him the *Father of all things*, imagining that he was produced by Humidity, which, according to Thales, was the first principle from which every thing was produced. Homer represents Juno visiting him at the remotest limits of the earth, and acknowledging him and Thetis as the parents of the gods. He was represented with a bull's head, as an emblem of the rage and bellowing of the ocean when agitated by a storm.

OCELLUS *the* LUCANIAN, an ancient Greek philosopher of the school of Pythagoras, who lived before Plato. His work περι τυ Παντος, or "the Universe," is the only piece of his which is come down entire to us; and was written originally in the Dorci dialect, but was translated by another hand into the Attic. William Christian, and after him Lewis Nogarola, translated this work into Latin; and we have several editions of it, both in Greek and Latin.

OCHLOCRACY, that form of government wherein the populace have the chief administration of affairs.

OCHRE, in natural history, a genus of earths, slightly coherent, and composed of fine, smooth, soft, argillaceous particles, rough to the touch, and readily diffusible in water. Ochres are of various colours, as red, blue, yellow, brown, green, &c.

OCKLEY (Simon), a learned orientalist, was born at Exeter, in 1678, and educated at Queen's college, Cambridge, where he distinguished himself by his intense application to literature. At the usual time he took the degrees in arts, and that of bachelor in divinity; but marrying very young, was precluded from a fellowship in his college, and this occasioned his being afterwards involved in many difficulties. In 1705, he was presented to the vicarage of Swavesey in Cambridgeshire; and in 1711, he was chosen Arabic professor of the university; but afterwards had the misfortune to be confined for some time in Cambridge-castle for debt. The above preferments, however, he enjoyed till his death, which happened on the 9th of August 1720. He wrote, 1. *Introductio ad Linguas Orientales*. 2. The history of the present Jews throughout the world; translated from the Italian of Leo Modena, a Venetian rabbi. 3. The improvement of human reason, exhibited in the life of Hai Ebn Yokdhan, translated from the Arabic. 4. An account of South-west Barbary, containing what is most remarkable in the kingdoms of Fez and Morocco; written by a person who had been a slave there a considerable time, and translated from his manuscript. 5. The history of the Saracens, collected from the most authentic Arabic authors, in 2 vols 8vo. He was not only well skilled in the learned languages; but also in the modern, as French, Spanish, Italian, &c.

OCTAETARIDES, in chronology, denotes a cycle of eight years, at the end of which three entire lunar months were added. This cycle was used at Athens till Meton discovered the golden number.

OCTAGON, or OCTOGON, in geometry, is a figure of eight sides and angles; and this, when all the sides and angles are equal, is called a *regular octagon*, or one that may be inscribed in a circle.

OCTAGON, in fortification, denotes a place that has eight bastions. See FORTIFICATION.

OCTAHEDRON, or OCTAEDRON, in geometry, one

one of the five regular bodies, consisting of eight equal and equilateral triangles.

OCTANDRIA (οκτω, "eight," and ανηρ, a "man, or husband,") the eighth class in Linnæus sexual system; consisting of plants with hermaphrodite flowers, which are furnished with eight stamina, or male organs of generation. See BOTANY, p. 1292.

OCTANT, or OCTILE, in astronomy, that aspect of two planets, wherein they are distant an eighth part of a circle, or 45°, from each other.

OCTAPLA, in matters of sacred literature, denotes a polyglot bible, consisting of eight columns, and as many different versions of the sacred text; viz. the original Hebrew both in Hebrew and Greek characters, Greek versions, &c.

OCTATEUCH, an appellation given to the eight first books of the Old Testament.

OCTAVE, in music. See INTERVAL.

OCTOBER, in chronology, the tenth month of the Julian year, consisting of 31 days; it obtained the name of *October*, from its being the eighth month in the kalendar of Romulus.

OCTOSTYLE, in the ancient architecture, is the face of an edifice adorned with eight columns.

OCULUS, the EYE, in anatomy. See there, n° 406.

OCULUS *Beli*, in natural history, one of the semi-pellucid gems, of a greyish white colour, variegated with yellow, and with a black central nucleus: it is of a roundish form, and its variegations very beautifully represent the pupil and iris of the eye; whence the name.

OCULUS *Cati*. See ASTERIA.

OCULUS *Mundi*, one of the semi-pellucid gems, of a whitish-grey colour, without any variegations.

OCYMUM, BASIL; a genus of the gynospermia order, belonging to the didynamia class of plants. There are eight species, all of them natives of warm climates, rising from six inches to two feet in height, and having a strong aromatic smell, resembling that of cloves. One of the species is used in the kitchen, particularly by the French cooks, who make great use of it in their soups and sauces. This rises about ten inches high, sending out branches by pairs opposite, from the bottom; the stalks and branches are four-cornered; the leaves are oval, spear-shaped, ending in acute points, and are indented on their edges; the whole plant is hairy, and has a strong scent of cloves too powerful for most persons, but to some it is very agreeable. These plants are propagated by seeds, and will thrive in this country in the open air, and will even ripen their seeds if placed in a stove or airy glass-case.

OCZAKOW, or OCZAKOFF, a town of Turky in Europe, and capital of a Sangiack of the same name, inhabited by Tartars. During a late war, here was a Turkish garrison of 20,000 men. However, it was taken by the Russians in 1737, and all those that resisted were put to the sword. The Russians themselves lost 18,000 men in the assault. The Turks returned the same year with 70,000 men to retake it; but were obliged to retire, after the loss of 20,000. In 1738, the Russians withdrew their garrison, and demolished the fortifications. It is seated on the river Bog, to the west of the Nieper, or rather where they both unite and fall into the Black Sea. It is 42 miles south-west of Bialagrod, and 190 north by east of Constantinople. E. Long. 30. 0. N. Lat. 46. 30.

ODA, in the Turkish seraglio, signifies a class, order, or chamber. The grand signior's pages are divided into five classes or chambers. The first, which is the lowest in dignity, is called the *great oda*, from the great number of persons that compose it: these are the juniors, who are taught to read, write, and speak the languages. The second is called the *little oda*, where, from the age of 14 or 15 years, till about 20, they are trained up to arms, and the study of all the polite learning the Turks are acquainted with. The third chamber, called *kilar oda*, consists of 200 pages, which, besides their other exercises, are under the command of the kilardgi-bachi, and serve in the pantry and fruitery. The fourth consists only of 24, who are under the command of the khazineda-bachi, and have charge of the treasure in the grand signior's apartment, which they never enter with cloaths that have pockets. The fifth is called *kas-oda*, or *privy-chamber*; a•d is composed of only 40 pages who attend in the prince's chamber. Every night eight of these pages keep guard in the grand signior's bed-chamber, while he sleeps: they take care that the light, which is constantly kept in the room, does not glare in his eyes, lest it should awake him; and if they find him disturbed with troublesome dreams, they cause him to be awaked by one of their agas.

ODA-*Bachi*, or *Oddobassi*, among the Turks, an officer equivalent to a serjeant or corporal among us.

ODE, in poetry, a song, or composition proper to be sung. See POETRY.

ODENSEE, a considerable town of Denmark, in the Isle of Funen, with a bishop's see. E. Long. 10. 27. N. Lat. 55. 28.

ODER, a river of Germany, which has its source near a town of the same name in Silesia, and on the confines of Moravia. It runs north through that province, and then into the Marche of Brandenburg and Pomerania, where it forms a large lake, afterwards falling into the Baltic Sea by three mouths; between which lie the islands Usedom and Wolin. It passes by several towns; as Ratibor, Oppelen, Breslau, Glogau, and Crossen, in Silesia; Francfort, Lebus, and Custrin, in Brandenburg; and Gartz, Stetin, Cammin, Wallin, Usedom, and Wolgast, in Pomerania.

ODEUM, in Grecian antiquity, a music-theatre, built by Pericles; the inside of which was filled with seats and ranges of pillars, and on the outside the roof descended shelving downwards from a point in the centre, with many bendings, in imitation of the king of Persia's pavilion. Here the musical prizes were contended for; and here also, according to Aristophanes, was a tribunal.

De ODIO *et Atia*. See *False* IMPRISONMENT.

The writ *de odio et atia* was anciently used to be directed to the sheriff, commanding him to inquire whether a prisoner charged with murder was committed upon just cause of suspicion, or merely *propter odium et atiam*, for hatred and ill-will; and if upon the inquisition due cause of suspicion did not then appear, then there issued another writ for the sheriff to admit him to bail. This writ, according to Bracton, ought not to be denied to any man; it being expressly ordered

to be made out *gratis*, without any denial, by *magna carta*, c. 26. and ſtatute Weſtm. 2. 13 Edw. I. c. 29. But the ſtatute of Gloceſter, 6 Edw. I. c. 9. reſtrained it in the caſe of killing by miſadventure or ſelf-defence, and the ſtatute 28 Edw. III. c. 9. aboliſhed it in all caſes whatſoever: but as the ſtat. 42 Ed. III. c. 1. repealed all ſtatutes then in being, contrary to the great charter, Sir Edward Coke is of opinion that the writ *de odio et atia* was thereby revived. See HABEAS *Corpus*.

ODO (St), ſecond abbot of Clugni in France, was illuſtrious for learning and piety in the 10th century. The ſanctity of his life contributed greatly to enlarge the congregation of Clugni; and he was ſo eſteemed, that popes, biſhops, and ſecular princes, uſually choſe him the arbiter of their diſputes. He died about the year 942, and his works are printed in the Bibliotheque of Clugni.

ODO *Cantianus*, ſo called as being a native of Kent, in England, was a Benedictine monk in the 12th century, in which order his learning and eloquence raiſed him to the dignity of prior and abbot. Archbiſhop Becket was his friend, and his panegyric was made by John of Saliſbury. He compoſed Commentaries on the Pentateuch, and the Second Book of Kings; Moral Reflections on the Pſalms; treatiſes intitled, *De onere Philiſtim; De moribus Eccleſiaſticis; De vitiis et virtutibus Animæ*, &c.

ODONTALGIA, the TOOTHACH. See MEDICINE, n° 314. and p. 4869.

ODONTOIDE, in anatomy, an appellation given to the proceſs of the ſecond vertebra of the neck, from its reſemblance to a tooth.

ODOROUS, or ODORIFEROUS, appellations given to whatever ſmells ſtrongly, whether they be fetid or agreeable; but chiefly to things whoſe ſmell is briſk and agreeable.

ODYSSEY, a celebrated epic poem of Homer, wherein are related the adventures of Ulyſſes in his return from the ſiege of Troy.

OECONOMICS, the art of managing the affairs of a family, or community; and hence the perſon who takes care of the revenues and other affairs of churches, monaſteries, and the like, is termed *œconomus*.

OECONOMY, denotes the prudent conduct, or diſcreet and frugal management, whether of a man's own eſtate, or that of another.

Animal OECONOMY, comprehends the various operations of nature in the generation, nutrition, and preſervation of animals †. The doctrine of the animal œconomy is nearly connected with phyſiology, which explains the ſeveral parts of the human body, their ſtructure, uſe, &c. See ANATOMY and MEDICINE.

† See *Generation*, *Nutrition*, &c.

OECUMENICAL, ſignifies the ſame with *general* or *univerſal;* as, œcumenical council, biſhop, &c.

OEDEMA, or PHLEGMATIC TUMOUR, in medicine and ſurgery, a ſort of tumour attended with paleneſs and cold, yielding little reſiſtance, retaining the print of the finger when preſſed with it, and accompanied with little or no pain.

This tumour obtains no certain ſituation in any particular part of the body, ſince the head, eye-lids, hands, and ſometimes part, ſometimes the whole body, is afflicted with it. When the laſt mentioned is the caſe, the patient is ſaid to be troubled with a cachexy, leucophlegmatia, or dropſy. But if any particular part is more ſubject to this diſorder than another, it is certainly the feet, which are at that time called *ſwelled* or *œdematous feet*.

OEDIPUS, the unfortunate king of Thebes, whoſe hiſtory is partly fabulous, flouriſhed about 1266 B. C. It is ſaid he was given by his father to a ſhepherd, who was ordered to put him to death, in order to prevent the misfortunes with which he was threatened by an oracle. But the ſhepherd being unwilling to kill him with his own hands, tied him by the feet to a tree, that he might be devoured by wild beaſts. The infant was, however, found in this ſituation by another ſhepherd named *Phorbas*, who carried him to Polybus king of Corinth; where the queen, having no children, educated him with as much care as if he had been her ſon. When he was grown up, he was informed that he was not the ſon of Polybus: on which, by order of the oracle, he went to ſeek for his father in Phocis; but ſcarce was he arrived in that country, when he met his father on the road, and killed him without knowing him. A ſhort time after, having delivered the country from the monſter called the *Sphinx*, he married Jocaſta, without knowing that ſhe was his mother, and had four children by her; but afterwards being informed of his inceſt, he quitted the throne, and, thinking himſelf unworthy of the light, put out his eyes. Eteocles and Polynices, who were celebrated amongſt the Greeks, were born of this inceſtuous marriage.

OELAND, an iſland of Sweden, ſeated on the Baltic ſea, between the continent of Gothland and the iſle of Gothland, in between 56° and 57° of north latitude, and between 17° and 18° of eaſt longitude. It is about 60 miles in length, and 15 in breadth; having a wholeſome air, and a fertile ſoil, with riſing hills, and ſeveral caſtles. It has no town of any great note.

OENANTHE, WATER DROPWORT; a genus of the digynia order, belonging to the pentandria claſs of plants. There are five ſpecies; of which the moſt remarkable is the crocata, or hemlock dropwort, growing frequently on the banks of ditches, rivers, and lakes, in many parts of Britain. The roots and leaves of this plant are a terrible poiſon; ſeveral perſons have periſhed by eating it through miſtake, either for water-parſnips or for celery, which laſt it reſembles pretty much in its leaves. So exceedingly deleterious is this plant, that Mr Lightfoot tells us, he has heard the late Mr Chriſtopher d'Ehret, the celebrated botanic painter, ſay, that while he was drawing it, the ſmell or effluvia only rendered him ſo giddy, that he was ſeveral times obliged to quit the room, and walk out in the freſh air to recover himſelf; but recollecting at laſt what might be the probable cauſe of his repeated illneſs, he opened the door and windows of the room, and the free air then enabled him to finiſh his work without any more returns of the giddineſs. Mr Lightfoot informs us, that he has given a ſpoonful of the juice of this plant to a dog, but without any other effect than that of making him very ſick and ſtupid. In about an hour he recovered; and our author has ſeen a goat eat it with impunity. To ſuch of the human ſpecies as have unfortunately eat any part of this plant, a vomit is the

moſt

moſt approved remedy.

OENOPTÆ, in Grecian antiquity, a kind of cenſors at Athens, who regulated entertainments, and took care that none drank too much, nor too little.

OENOTHERA, TREE-PRIMROSE; a genus of the monogynia order, belonging to the octandria claſs of plants. There are ſeven ſpecies; the moſt remarkable of which are,

1. The biennis, or common biennial tree-primroſe. It hath a long, thick, deeply-ſtriking root; crowned with many large, oval, ſpear-ſhaped, plane, ſpreading leaves; upright, thick, firm, rough, hairy ſtems, riſing three or four feet high; garniſhed with long, narrow, lanceolate, cloſe-fitting leaves, irregularly; and at all the axillas, from the middle upwards, large bright-yellow flowers.

2. Octovalvis, or octovalved, ſmooth, biennial tree-primroſe, hath upright, firm, ſomewhat hairy ſtems, riſing a yard high; oblong, ſpear-ſhaped, pointed, plane, ſmooth leaves; and at the axillas large bright-yellow flowers.

3. The fruticoſa, or ſhrubby, narrow-leaved, perennial tree-primroſe, hath long thick roots; upright, under-ſhrubby like red ſtems, two or three feet high; ſpear-ſhaped, lightly-indented leaves; and at the axillas pedunculated cluſters of yellow flowers, ſucceeded by pedicellated, acute-angled capſules.

4. The pumila, or low perennial tree-primroſe, hath fibrous roots, crowned with many oval, ſpear-ſhaped, cloſe-fitting leaves; ſlender herbaceous ſtems 10 or 12 inches long; garniſhed with ſpear-ſhaped, blunt, ſmooth leaves, having very ſhort foot-ſtalks; and at the axillas ſmalliſh bright-yellow flowers, ſucceeded by acute-angled capſules.

All theſe plants flower very profuſely in June and July, coming out almoſt half the length of the ſtalks from the axillas; and as the ſtalk advances in ſtature, new flowers are produced, ſucceeding thoſe below; in which order the plants continue flowering from about midſummer till October: each flower is moderately large and conſpicuous, conſiſting of four plane petals, which with the calix forms a very long tube below, and ſpreading above, generally expand moſt towards the evening; and are ſucceeded by plenty of ſeed in autumn for propagation.

Theſe plants are exotics from America; but are all very hardy, proſper in any common ſoil and ſituation, and have been long in the Engliſh gardens, eſpecially the three firſt ſorts; but the œnothera biennis is the moſt commonly known.

The firſt and ſecond ſpecies are biennial, and the third and fouth are perennial in root.

They are proper to be employed as plants of ornament for embelliſhing the pleaſure-garden; they may be placed any-where, and will effect a very agreeable variety three or four months with their plentiful blow of flowers.

The biennial kinds muſt be raiſed annually from ſeed, for they totally periſh after they have flowered. But the perennials, once raiſed, continue for years by the root.

The propagation of all the ſorts is by ſeed, and the perennials alſo by parting the roots.

OENOTRIA, an ancient name of Italy; ſo called from the *Oenotri*, (Virgil); inhabiting between Pæſtum and Tarentum, (Ovid). Originally Arcadians, (Dionyſius Halicarnaſſæus), who came under the conduct of Oenotrus ſon of Lycaon, 17 generations before the war of Troy, or 459 years, at 27 years each generation, and gave name to the people. Cato derives the name from *Oenotrus*, king of the Sabines and Etruſcans; but Varro from *Oenotrus*, king of the Latins; and Servius from the Greek name for wine, for which Italy was famous; of which opinion is Strabo.

OENOTRIDES (Strabo, Pliny), two ſmall iſlands in the Tuſcan ſea, over-againſt Velia, a town of Lucania, called *Pontia* and *Iſcia;* now *Penza* and *Iſchta*, on the coaſt of the Principato Citra, or to the weſt of Naples. So called from the *Oenotri*, an ancient people of Italy.

OESEL, an iſland of the Baltic ſea, at the entrance of the gulf of Livonia. It is about 70 miles in length, and 50 in breadth, and contains 10 pariſhes. It is defended by the fortreſſes of Airenſburg and Sonneburg. It is in between 22° and 24° of eaſt longitude, and between 58° and 59° of north latitude.

OESOPHAGUS, in anatomy, the GULA, or *Gullet*, is a membranaceous canal, reaching from the fauces to the ſtomach, and conveying into it the food taken in at the mouth. See ANATOMY, n° 353.

OESTRUS, in zoology, a genus of inſects belonging to the order of diptera. It has no mouth; but three punctures, without trunk or beak: Antennæ taper, proceeding from a lenticular joint. There are five ſpecies.

1. Bovis, the breeze or gad-fly. Thorax yellow, with a black tranſverſe line between the wings: Abdomen tawny, with fine black tranſverſe lines; laſt ſegment black: Wings white, with a brown tranſverſe line, and three brown ſpots. Size of the large blue fly. Depoſits its eggs under the ſkin on the backs of oxen, where the maggots are nouriſhed the whole winter till the month of June; and plague the cattle ſo all the ſummer, that they are obliged to fly for refuge into the water, and dare not quit it the whole day.

2. The hæmorrhoidalis. Body long, black, covered with tawny hair; middle of the thorax leſs hairy; wings immaculate; antennæ very ſhort: Length half an inch. Depoſits its eggs in the rectum of horſes, and occaſions great torment.

3. Ovis, the grey-fly. Spotted with black; front pale yellow; legs browniſh; wings with ſhort black veins: Length half an inch. Breeds in the frontal ſinus of ſheep; where the maggots, hatched from the eggs, lodge the whole winter, vellicating the internal membranes, and often bringing on death.

5. The naſalis. Body black; but the head, thorax, and abomen, covered with pale-red hair, except the firſt ſegment of the latter, which is covered with white hair; the wings immaculate. Breeds in the fauces of horſes, entering by their noſe.

5. The tarandi. Thorax yellow; with a black line between the wings, which are immaculate: abdomen tawny, laſt ſegment black. Infeſt the back of the rein-deer, ſo as greatly to retard the breed. The rein-deer of Lapland are obliged every year to fly to the

the Alpine mountains, to efcape the purfuit of thefe infects: yet a fourth part of their number perifh by them at two years old; the reft are emaciated, and have their fkins fpoiled.

OETA (Strabo, Ptolemy), a mountain of Theffaly, extending from Thermopylæ weftward to the Sinus Ambracius, and in fome meafure cutting at right angles the mountainous country ftretching out between Parnaffus to the fouth, and Pindus to the north. At Thermopylæ it is very rough and high, rifing and ending in fharp and fteep rocks, affording a narrow paffage between it and the fea from Theffaly to Locris, (Strabo): with two paths over it; the one above Trachis, very fteep and high; the other through the country of the Ænianes, much eafier and readier for travellers; by this it was that Leonidas was attacked in rear by the Perfians, (Paufanias). Here Hercules laid himfelf on the funeral pile, (Silius Italicus, Ovid); the fpot thence called *Pyra*, (Livy): who fays, that the extreme mountains to the eaft are called *Oeta;* and hence the poets allege, that day, night, fun, and ftars, arofe from Oeta, (Seneca, Statius, Silius Italicus, Catullus, Virgil's *Culex.)* Circumftances which fhew the height of this mountain.

OETING, a town of Germany, in Upper Bavaria, under the jurifdiction of Burkhaufen. It is divided into the upper and the lower town, and feated on the river Inn, eight miles weft of Burckhaufen. E. Long. 12. 47. N. Lat. 48. 0. There is a great refort of pilgrims to the old chapel.

Oeting, or *Oetingen*, a town of Germany, in the circle of Suabia, and capital of a county of the fame name, feated on the river Wirnitz. E. Long. 10. 45. N. Lat. 48. 52.

Oeting, a county of Germany, in the circle of Suabia, bounded on the north and eaft by Franconia; on the fouth by the duchy of Neuburg; and on the weft by that of Wirtemberg. It is about 40 miles from eaft to weft, and 20 from north to fouth.

OFFA's-dyke, an entrenchment caft up by Offa, a Saxon king, to defend England againft the incurfions of the Welch. It runs through Herefordfhire, Shropfhire, Montgomeryfhire, Denbighfhire, and Flintfhire.

OFFANTO, a river of Italy, in the kingdom of Naples. It rifes in the Appenine mountains, in the Farther Principato; and paffing by Conza, and Monte Verde, it afterwards feparates the Capitanata from the Bafilicata and the Terra-di-Barri, and then it falls into the gulf of Venice, near Salpe.

OFFENCE, in law, an act committed againft the law, or omitted where the law requires it.

OFFICE, a particular charge or truft, or a dignity attended with a public function. See Honour.—The word is primarily ufed in fpeaking of the offices of judicature and policy; as the office of fecretary of ftate, the office of a fheriff, of a juftice of peace, &c.

Office alfo fignifies a place or apartment appointed for officers to attend in, in order to difcharge their refpective duties and employments; as the fecretary's office, ordnance-office, excife-office, fignet-office, paper-office, pipe-office, fix-clerks office, &c.

Office, in architecture, denotes all the apartments appointed for the neceffary occafions of a palace or great houfe; as kitchen, pantries, confectionaries, &c.

Office, in the canon-law, is ufed for a benefice that has no jurifdiction annexed to it.

Duty upon Offices *and Penfions*, a branch of the king's extraordinary perpetual revenue, confifting in a payment of 1 s. in the pound (over and above all other duties) out of all falaries, fees, and perquifites, of offices and penfions payable by the crown. This highly-popular taxation was impofed by ftat. 31 Geo. II. c. 22. and is under the direction of the commiffioners of the land-tax.

OFFICER, a perfon poffeffed of a poft or office. See the preceding article.

The great officers of the crown, or ftate, are, The lord high-fteward, the lord high-chancellor, the lord high-treafurer, the lord-prefident of the council, the lord privy-feal, the lord-chamberlain, the lord high-conftable, and the earl-marfhal; each of which fee under its proper article.

Non-commiffioned Officers, are ferjeant-majors, quarter-mafter ferjeants, ferjeants, corporals, drum and fife majors; who are nominated by their refpective captains, and appointed by the commanding officers of regiments, and by them reduced without a court-martial.

Orderly non-commiffioned Officers, are thofe who are orderly, or on duty for that week; who, on hearing the drum beat for orders, are to repair to the place appointed to receive them, and to take down in writing, in the orderly book, what is dictated by the adjutant, or ferjeant-major: they are then immediately to fhew thefe orders to the officers of the company, and afterwards warn the men for duty.

Flag Officers. See Flag *Officers*, and Admirals.

General Officers, are thofe whofe command is not limited to a fingle company, troop, or regiment; but extends to a body of forces compofed of feveral regiments: fuch are the general, lieutenant-general, major-general, and brigadier.

Officers *of the Houfehold.* See the article Household.

Staff Officers, are fuch as, in the king's prefence, bear a white ftaff, or wand; and at other times, on their going abroad, have it carried before them by a footman bare-headed: fuch are the lord-fteward, lord-chamberlain, lord-treafurer, &c.

The white ftaff is taken for a commiffion; and, at the king's death, each of thefe officers breaks his ftaff over the hearfe made for the king's body, and by this means lays down his commiffion, and difcharges all his inferior officers.

Subaltern Officers are all who adminifter juftice in the name of fubjects; as thofe who act under the earl-marfhal, admiral, &c. In the army, the fubaltern officers are the lieutenants, cornets, enfigns, ferjeants, and corporals.

OFFICIAL, in the canon-law, an ecclefiaftical judge, appointed by a bifhop, chapter, abbot, &c. with charge of the fpiritual jurifdiction of the diocefe.

Official is alfo a deputy appointed by an archdeacon as his affiftant, who fits as judge in the archdeacon's

deacon's court.

OFFICINAL, in pharmacy, an appellation given to ſuch medicines, whether ſimple or compound, as are required to be conſtantly kept in the apothecaries ſhops. The *officinal ſimples* are appointed, among us, by the college of phyſicians; and the manner of making the compoſitions directed in their diſpenſatory. See PHARMACY.

OFFING, or OFFIN, in the ſea-language, that part of the ſea a good diſtance from ſhore, where there is deep water, and no need of a pilot to conduct the ſhip: thus, if a ſhip from ſhore be ſeen ſailing out to ſeaward, they ſay, *ſhe ſtands for the offing;* and if a ſhip, having the ſhore near her, have another a good way without her, or towards the ſea, they ſay, *that ſhip is in the offing*.

OFF-SETS, in gardening, are the young ſhoots that ſpring from the roots of plants; which being carefully ſeparated, and planted in a proper ſoil, ſerve to propagate the ſpecies.

OFF-SETS, in ſurveying, are perpendiculars let fall, and meaſuring from the ſtationary lines to the hedge, fence, or extremity of an incloſure.

OGEE, or O. G. in architecture, a moulding conſiſting of two members, the one concave, and the other convex; or of a round and hollow, like an S. See ARCHITECTURE.

OGILBY (John), an eminent writer, was born in or near Edinburgh, about the 17th of November 1600. His father having ſpent his eſtate, and being priſoner in the King's Bench for debt, could contribute but little to his education; however, he obtained ſome knowledge in the Latin grammar, and afterwards ſo much money as to procure his father's diſcharge from priſon, and to bind himſelf an apprentice to a dancing-maſter in London; when, by his dexterity in his profeſſion, and his complaiſant behaviour to his maſter's ſcholars, he obtained money to buy out the remainder of his time, and to ſet up for himſelf. But being afterwards appointed to dance in the duke of Buckingham's great maſk, he by a falſe ſtep ſtrained a vein in the inſide of his leg, which occaſioned his being ever after ſomewhat lame. When Thomas earl of Strafford was made lord lieutenant of Ireland, he was entertained as a dancing-maſter in his family, and made one of the earl's troop of guards; at which time he compoſed a humorous piece called the *Character of a Trooper*. He was ſoon after appointed maſter of the revels in Ireland, and built a theatre at Dublin. About the time of the concluſion of the war in England, he left Ireland, and, being ſhipwrecked, came to London in a neceſſitous condition; but ſoon after walked to Cambridge, where, being aſſiſted by ſeveral ſcholars, he became ſo complete a maſter of the Latin tongue, that in 1649 he publiſhed a tranſlation of Virgil. He ſoon after learned Greek; and in 1660 publiſhed in folio, a tranſlation of Homer's Iliad, with Annotations. About two years after, he went into Ireland, where he was made maſter of the revels by patent. He then built another theatre in Dublin, which coſt him about 1000 l. He publiſhed at London in folio, a tranſlation of Homer's Odyſſey, with Annotations; and afterwards wrote two heroic poems, intitled the *Epheſian Matron*, and the *Roman Slave*. He next compoſed the Carolics, an epic poem, in 12 books, in honour of king Charles I. but this was entirely loſt in the fire of London; when Mr Ogilby's houſe in White Fryars was burnt down, and his whole fortune, except to the value of five pounds, deſtroyed. He, however, ſoon procured his houſe to be re-built, ſet up a printing-office within it, was appointed his majeſty's coſmographer and geographic printer, and printed ſeveral great works, tranſlated or collected by himſelf and his aſſiſtants, particularly his Atlas. He died in 1676.

OGIVE, in architecture, an arch or branch of a Gothic vault; which, inſtead of being circular, paſſes diagonally from one angle to another, and forms a croſs with the other arches. The middle, where the ogives croſs each other, is called the *key;* being cut in form of a roſe, or a *cul de lampe*. The members or mouldings of the ogives are called *nerves*, *branches*, or *reins;* and the arches which ſeparate the ogives, *double arches*.

OGYGES, king of the Thebans, or, as others, of Ogygia and Actæ, afterwards called *Bœotia* and *Attica*. He is recorded to have been the firſt founder of Thebes and Eleuſin. The famous deluge happened in his time, in which ſome ſay he periſhed with all his ſubjects, 1796 B. C.

OGYGIA, (Homer), the iſland of Calypſo; placed by Pliny in the Sinus Scylaceus, in the Ionian ſea, oppoſite to the promontory Lacinium; by Mela in the ſtrait of Sicily, calling it *Ææe;* which others place at the promontory Circeium, and call it the iſland of *Circe*.

OGYGIA, the ancient name of Thebes in Bœotia; ſo called from Ogyges, an ancient king, under whom happened a great deluge, 1020 years before the firſt olympiad.

OHIO, a river of North America, called by the French the *Beautiful River*, has its ſource between the Allegany mountains and the lake Erie; and running ſouth-weſt through a moſt delightful country, as alſo receiving many ſmaller rivers in its paſſage, at length falls into the Miſſiſippi, in about 37 degrees of latitude. The French had ſeveral forts on and near it; but the whole country through which it flows was ceded by the peace of 1763 to the Britiſh.

O-HETEROA, one of the South Sea iſlands lately diſcovered, is ſituated in W. Long. 150. 47. S. Lat. 22. 27. It is neither fertile nor populous; nor has it an harbour or anchorage fit for ſhipping, and the diſpoſition of the people is hoſtile to ſuch as viſit them.

OIL, in natural hiſtory, an unctuous inflammable ſubſtance, drawn from ſeveral natural bodies, as animal and vegetable ſubſtances.

Animal oils are their fats, which are originally vegetable oils: all animal ſubſtances yield them, together with their volatile ſalts, in diſtillation.

Vegetable oils are obtained by expreſſion, infuſion, and diſtillation.

The oils by expreſſion are obtained from the ſeed, leaves, fruit, and bark of plants; thus, the ſeed of muſtard, and of the ſun-flower, almonds, nuts, beech-maſt, &c. afford a copious oil by expreſſion; and the leaves of roſemary, mint, rue, wormwood, thyme, ſage, &c. the berries of juniper, olives, Indian cloves, nutmeg, mace, &c. the barks of cinnamon, ſaſſafras, and clove, yield a conſiderable proportion of eſſential oil by diſtillation.

Oil. Oil.

The method of procuring oils by expreſſion is very ſimple: thus, if either ſweet or bitter almonds, that are freſh, be pounded in a mortar, the oil may be forced out with a preſs, not heated: and in the ſame manner ſhould the oil be preſſed from linſeed and muſtard. The avoiding the uſe of heat in preparing theſe oils, intended for internal medicinal uſe, is of great importance, as heat gives them a very prejudicial rancidneſs.

This method holds of all thoſe vegetable matters that contain a copious oil, in a looſe manner, or in certain cavities or receptacles; the ſides whereof being broke, or ſqueezed, makes them let go the oil they contain: and thus the zeſt or oil of lemon-peel, orange-peel, citron-peel, &c. may be readily obtained by preſſure, without the uſe of fire. But how far this method of obtaining oils may be applied to advantage, ſeems not hitherto conſidered. It has been commonly applied to olives, almonds, linſeed, rape-ſeed, beech-maſt, ben-nuts, walnuts, bay-berries, mace, nutmeg, &c. but not, that we know of, to juniper-berries, caſhew-nuts, Indian cloves, pine apples, and many other ſubſtances that might be enumerated, both of foreign and domeſtic growth. It has, however, been of late ſucceſsfully applied to muſtard-ſeed, ſo as to extract a curious gold-coloured oil, leaving a cake behind, fit for making the common table-muſtard.

Certain dry matters, as well as moiſt ones, may be made to afford oils by expreſſion, by grinding them into a meal, which being ſuſpended to receive the vapour of boiling water, will thus be moiſtened ſo as to afford an oil in the ſame manner as almonds; and thus an oil may be procured from linſeed, hemp-ſeed, lettuce-ſeed, white-poppy ſeed, &c.

As to the treatment of oils obtained by expreſſion, they ſhould be ſuffered to depurate themſelves by ſtanding in a moderately cool place, to ſeparate from their water, and depoſit their fæces; from both which they ought to be carefully freed. And if they are not thus rendered ſufficiently pure, they may be waſhed well with freſh water, then thoroughly ſeparated from it again by the ſeparating-glaſs, whereby they will be rendered bright and clear.

The next claſs of oils are thoſe made by infuſion, or decoction, wherein the virtues of ſome herb or flower is drawn out in the oil; as the oils of roſes, chamæmile, hypericum, alder, &c. However, theſe require to be differently treated: thus, for the ſcented flowers, particularly roſes, inſolation does beſt; becauſe much boiling would exhale their more fragrant parts: but oils impregnated with green herbs, as thoſe of chamæmile and alder, require long boiling, before they receive the green colour deſired. And, in general, no oils will bear to be boiled any longer than there remains ſome aqueous humidity, without turning black.

There are many compound oils prepared in the ſame manner, *viz.* by boiling and inſolation, and then ſtraining off the oil for uſe.

The ſame contrivance has likewiſe its uſe in making eſſences for the ſervice of the perfumer; not only where eſſential oils cannot be well obtained in ſufficient quantities, but alſo where they are too dear. The eſſential oil of jeſſamine-flowers, honey-ſuckles, ſweet-briar, damaſk-roſes, lilies of the valley, &c. are either extremely dear, or ſcarcely obtainable by diſtillation; and, in ſome of them, the odorous matter is ſo ſubtile, as almoſt to be loſt in the operation. But if theſe flowers be barely infuſed in fine oil of nuts, or oil of ben, drawn without heat, and kept in a cool place, their ſubtile odorous matter will thus paſs into the oil, and richly impregnate it with their flavour. And theſe eſſences may be rendered ſtill more perfect by ſtraining off the oil at firſt put on, and letting it ſtand again, without heat, upon freſh flowers; repeating the operation twice or thrice.

Oils or fats may likewiſe be obtained, by boiling and expreſſion, from certain animal-ſubſtances; for the membranes which contain the fat, being chopped ſmall, and ſet in a pan over the fire, become fit for the canvas bag, and, by preſſure, afford a large quantity of fat; as we ſee in the art of chandlery, which thus extracting the oily matter, leaves a cake behind, commonly called *graves*.

As to the eſſential oils of vegetables, they are obtained by diſtillation with an alembic and a large refrigeratory. Water muſt be added to the materials, in ſufficient quantity to prevent their burning; and they ſhould be macerated or digeſted in that water, a little time before diſtillation. The oil comes over with the water; and either ſwims on the top, or ſinks to the bottom, according as it is ſpecifically heavier or lighter than water.

This proceſs is applicable to the diſtilling of the eſſential oils from flowers, leaves, barks, roots, woods, gums, and balſams, with a ſlight alteration of circumſtances, as by longer digeſtion, briſker diſtillation, &c. according to the tenacity and hardneſs of the ſubject, the ponderoſity of the oil, &c.

Eſſential oils may be divided into two claſſes, according to their different ſpecific gravities; ſome floating upon water, and others readily ſinking to the bottom. Thus, the eſſential oils of cloves, cinnamon, and ſaſſafras, readily ſink; whereas thoſe of lavender, marjoram, mint, &c. ſwim in water: the lighteſt of theſe eſſential oils is, perhaps, that of citron-peel, which even floats in ſpirit of wine; and the heavieſt ſeems to be oil of ſaſſafras.

For obtaining the full quantity of the more ponderous oils from cinnamon, cloves, ſaſſafras, &c. it is proper to reduce the ſubjects to powder; to digeſt this powder for ſome days in a warm place, with thrice its quantity of ſoft river-water, made very ſaline by the addition of ſea-ſalt, or ſharp with oil of vitriol; to uſe the ſtrained decoction, or liquor left behind in the ſtill, inſtead of common water, for freſh digeſtion; to uſe for the ſame purpoſe the water of the ſecond running, after being cleared of its oil; not to diſtil too large a quantity of theſe ſubjects at once; to leave a conſiderable part of the ſtill, or about one fourth, empty; to uſe a briſk fire, or a ſtrong boiling heat, at the firſt, but to ſlacken it afterwards; to have a low ſtill-head, with a proper internal ledge and current leading to the noſe of the worm; and, finally, to cohobate the water, or pour back the liquor of the ſecond running upon the matter in the ſtill, repeating this once or twice.

The directions here laid down for obtaining the ponderous oils to advantage, are eaſily transferred to the obtaining of the lighter; ſo that we need not dwell particularly upon them.

Many of the eſſential oils being dear, it is a very common practice to adulterate or debaſe them ſeveral ways, ſo as to render them cheaper both to the ſeller and the buyer. Theſe ſeveral ways ſeem reducible to three general kinds, each of which has its proper method of detection, viz. 1. With expreſſed oils. 2. With alcohol. And, 3. With cheaper eſſential oils.

If an eſſential oil be adulterated with an expreſſed oil, it is eaſy to diſcover the fraud; by adding a little ſpirit of wine to a few drops of the ſuſpected eſſential oil, and ſhaking them together; for the ſpirit will diſſolve all the oil that is eſſential, or procured by diſtillation, and leave all rhe expreſſed oil that was mixed with it, untouched.

If an eſſential oil be adulterated with alcohol, or rectified ſpirit of wine, it may be done in any proportion, up to that of an equal quantity, without being eaſily diſcoverable either by the ſmell or taſte: the way to diſcover this fraud, is to drop a few drops of the oil into a glaſs of fair water; and if the oil be adultered with ſpirit, the water will immediately turn milky, and, by continuing to ſhake the glaſs, the whole quantity of ſpirit will be abſorbed by the water, and leave the oil pure at top.

Finally, if an eſſential oil be adulterated by a cheaper eſſential oil, this is commonly done very artfully: the method is to put fir-wood, turpentine, or oil of turpentine, into the ſtill, along with the herbs to be diſtilled for their oil, ſuch as roſemary, lavender, origanum, &c. and by this means, the oil of turpentine diſtilled from theſe ingredients, comes over in great quantity, and intimately blended with the oil of the genuine ingredient. The oils thus adulterated always diſcover themſelves in time, by their own flavour being overpowered by the turpentine-ſmell: but the ready way to detect the fraud, is to drench a piece of rag, or paper, in the oil, and hold it before the fire; for thus the grateful flavour of the plant will fly off, and leave the naked turpentine-ſcent behind.

The virtues of oils being the ſame with thoſe of the ſubſtances from whence they are obtained, may be learned under their ſeveral articles.

Method of Purifying Rancid OILS. See CHEMISTRY, n° 497.

OINTMENT, in pharmacy. See UNGUENT.

OKEHAM, the capital of Rutlandſhire, in England, ſeated in a rich and pleaſant valley, called the *vale of Catmus*. It is pretty well built, has a good church, a free-ſchool, and an hoſpital. W. Long. 0. 45. N. Lat. 52. 40.

OKINGHAM, OCKINGHAM, or *Woxingham*, a large town of Berkſhire, in England, noted for the manufacture of ſilk ſtockings. W. Long. 0. 50. N. Lat. 51. 26.

OLAUS MAGNUS, archbiſhop of Upſal in Sweden, ſucceeded his brother John Magnus in 1544. He appeared with great credit at the council of Trent in 1546, and ſuffered much afterward for the Catholic religion. We have of his writing, A Hiſtory of the Manners, Cuſtoms, and Wars of the Northern Nations of Europe.

OLD-AGE. See LONGEVITY.

OLD-*Man of the Mountain*. See ASSASINS.

OLDCASTLE (Sir John), called the *Good Lord Cobham*, was born in the reign of Edward III. and was the firſt author as well as the firſt martyr among the Engliſh nobility: he obtained his peerage by marrying the heireſs of that Lord Cobham who with ſo much virtue and patriotiſm oppoſed the tyranny of Richard II. By his means the famous ſtatute againſt proviſors was revived, and guarded againſt by ſeverer penalties; he was one of the leaders of the reforming party; was at great expence in procuring and diſperſing copies of Wickliffe's writings among the people, as well as by maintaining a number of his diſciples as itinerant preachers. In the reign of Henry V. he was accuſed of hereſy; the growth of which was attributed to his influence. Being a domeſtic in the king's court, the king delayed his proſecution that he might reaſon with him himſelf; but not being able to reclaim him to the church of Rome, he in great diſpleaſure reſigned him to its cenſure He was apprehended and condemned for hereſy; but eſcaping from the tower, lay concealed for four years in Wales, until the rumour of a pretended conſpiracy was raiſed againſt him, and a price ſet upon his head: he was at laſt ſeized, and executed in St Giles's Fields; being hung alive in chains upon a gallows, and burned by a fire placed underneath. He wrote "Twelve Concluſions, addreſſed to the Parliament of England."

OLDENBURG (Henry), a learned German gentleman in the 17th century, was deſcended from the noble family of his name, who were earls of the county of Oldenburg, in the north part of Weſtphalia for many generations. He was born in the duchy of Bremen in the Lower Saxony; and during the long Engliſh parliament in king Charles I's. time, was appointed conſul for his countrymen, at London, after the uſupation of Cromwell: but being diſcharged of that employ, he was made tutor to the lord Henry O'Bryan, an Iriſh nobleman, whom he attended to the univerſity of Oxford, where he was admitted to ſtudy in the Bodleian library in the beginning of the year 1656, when Cromwell was vice-chancellor. He was afterwards tutor to William lord Cavendiſh, and was acquainted with Milton the poet. During his reſidence at Oxford, he became alſo acquainted with the members of that ſociety there, which gave birth to the royal ſociety; and upon the foundation of this latter, he was elected fellow; and when the ſociety found it neceſſary to have two ſecretaries, he was choſen aſſiſtant-ſecretary to Dr Wilkins. He applied himſelf with extraordinary diligence to the buſineſs of his office, and began the publication of the Philoſophical Tranſactions with N° 1. in 1664. In order to diſcharge this taſk with greater credit to himſelf and the ſociety, he held a correſpondence with more than ſeventy learned perſons, and others, upon a vaſt variety of ſubjects, in different parts of the world. This fatigue would have been inſupportable, had not he, as he told Dr Liſter, managed it ſo as to make one letter anſwer another, and that, to be always freſh, he never read a letter before he had pen, ink and paper, ready to anſwer it forthwith; ſo that the multitude of his letters cloyed him not, nor ever lay upon his hands. Among others, he was a conſtant correſpondent of Mr Robert Boyle, with whom he had a very intimate friendſhip; and he tranſlated ſeveral of that ingenious gentleman's works into Latin.

Mr Oldenburg continued to publifh the Tranfactions, as before, to N° xxxvi. June 25, 1677. After which the publication was difcontinued till the January following, when it was again refumed by his fucceffor in the fecretary's office, Mr Nehemiah Grew, who carried it on till the end of February 1678. Our author dying at his houfe at Charleton, near Greenwich in Kent, in the month of Auguft that year, was interred there.

OLDHAM (John), an eminent Englifh poet in the 17th century, fon of a non-conformift minifter, was educated under his father, and then fent to Edmund-hall in Oxford. He became ufher to the free-fchool at Croyden in Surry; where he received a vifit from the earls of Rochefter and Dorfet, Sir Charles Sedley, and other perfons of diftinction, merely upon the reputation of fome verfes which they had feen in manufcript. He was tutor to feveral gentlemens fons fucceffively; and having faved a fmall fum of money, came to London, and became a perfect votary to the bottle, being an agreeable companion. He was quickly found out here by the noblemen who had vifited him at Croydon, who brought him acquainted with Mr Dryden. He lived moftly with the earl of Kingfton at Holme-Pierpoint in Nottinghamfhire, where he died of the fmall-pox in 1683, in the 30th year of his age. His acquaintance with learned authors appears by his fatires againft the Jefuits, in which there is as much learning as wit difcovered. Mr Dryden efteemed him highly. His works are printed in 2 vols 12mo. They chiefly confift of fatires, odes, tranflations, paraphrafes of Horace and other authors, elegiac verfes, imitations, parodies, familiar epiftles, &c.

OLDMIXON (John) was defcended from an ancient family in Somerfetfhire: he was a violent party-writer and malevolent critc, who would fcarcely have been remembered, if Pope, in refentment of his abufe, had not condemned him to immortality in his Dunciad. His party-writings procured him a place in the revenue at Liverpool, where he died at an advanced age in the year 1745. Befides his fugitive temporary pieces, he wrote a hiftory of the Stuarts in folio; a critical hiftory of England, 2 vols 8vo; a volume of poems, fome dramatic pieces, &c.; none of them worthy of notice, his principal talent being that of falfifying hiftory.

OLD-WIFE, or *Wraffe*, See LABRUS.

OLD-WIFE *Fifh*. See BALISTES.

OLEA, the OLIVE-TREE; a genus of the monogynia order, belonging to the diandria clafs of plants.

There are two fpecies, 1. The Europea, or common olive-tree, rifes with upright folid ftems, branching numeroufly on every fide, 20 or 30 feet high; fpear-fhaped, ftiff, oppofite leaves, two or three inches long, and half an inch or more broad; and at the axillas fmall clufters of white flowers, fucceeded by oval fruit.

This fpecies is the principal fort cultivated for its fruit; the varieties of which are numerous, varying in fize, colour, and quality.

It is a native of the fouthern warm parts of Europe, and is cultivated in great quantities in the fouth of France, Italy, and Portugal, for the fruit to make the olive-oil, which is in fo great repute, and is tranfported to all parts. to the great advantage of thofe countries where the trees grow in the open ground: the green fruit is alfo in much efteem for pickling, of which we may fee plenty in the fhops.

2. The capenfis, or cape box-leaved olive, rifes with fhrubby ftems, branching numeroufly from the bottom, fix or feven feet high; fmall, oval, thick, ftiff, fhining leaves; and at the axillas fmall clufters of whitifh flowers; fucceeded by fmall fruit of inferior value.

Thefe plants in this country muft be kept principally in pots for moving to fhelter of a green-houfe in winter; for they are too render to profper well in the open ground here: though fometimes they are planted againft a warm fouth wall, and fheltered occafionally from froft in winter, by mulching the roots, and matting their tops; whereby they may be preferved, and will fometimes produce fruit for pickling: a very fevere winter, however, often kills or greatly injures their young branches; therefore let the principal part be potted in rich earth, and placed among the green-houfe fhrubs, and managed as others of that kind.

Thefe trees are often fent over from Italy to the Italian warehoufes in London, along with orange-trees, &c. where pretty large plants may be purchafed reafonably, which fhould be managed as directed for orange-trees that are imported from the fame country. See CITRUS.

Their propagation here is commonly by layers.

The laying is performed on the young branches in fpring. Give plenty of water all fummer, and they will fometimes be rooted fit for potting-off by autumn; but fometimes they require two fummers to be rooted effectually: when, however, they are properly rooted take them off early in autumn, and pot them feparately, give water, and place them in the fhade till they have taken frefh root; and in October remove them into the green-houfe, &c.

Thofe you intend to plant in the open ground, as before fuggefted, fhould be kept in pots; in order to have occafional fhelter of a garden-frame two or three years, till they have acquired fome fize, and are hardened to the full air; then tranfplant them into a warm border againft a wall: mulch their roots in winter, and mat their tops in frofty weather.

Olives have an acrid, bitter, extremely difagreeable tafte: pickled (as we receive them from abroad) they prove lefs difagreeable. The Lucca olives, which are fmaller than the others, have the weakeft tafte; the Spanifh, or larger, the ftrongeft; the Provence, which are of a middling fize, are generally the moft efteemed.

The oil obtained from this fruit has no particular tafte or fmell, and does not greatly differ in quality from oil of almonds. Authors make mention of two forts of this oil, one expreffed from the olives when fully ripe, which is our common oil olive; the other, before it has grown ripe; this is called *oleum immaturum*, and *omphacinum*. Nothing is met with in the fhops under this name; and Lemery affirms, that there is no fuch oil, unripe olives yielding only a vifcid juice to the prefs. From the ripe fruit, two or three forts are obtained, differing in degree of purity: the pureft runs by light preffure; the remaining magma, heated and preffed

fed more strongly, yields an inferior sort, with some dregs at the bottom, called *amurca*. All these oils contain a considerable quantity of aqueous moisture, and a mucilaginous substance, which subject them to run into a putrid state: to prevent this, the preparers add some sea-salt, which, imbibing the aqueous and mucilaginous parts, sinks with them to the bottom; by this means the oil becomes more homogene, and consequently less susceptible of alteration. In its passage to us, some of the salt, thrown up from the bottom by the shaking of the vessel, is sometimes mixed with and detained in the oil, which, in our colder climate, becomes too thick to suffer it freely to subside; and hence the oil is sometimes met with of a manifestly saline taste. Oil- olive is used in the simple balsam of sulphur, Locatelli's balsam, and several ointments. It is oftener employed in this last intention than the other expressed oils, but more rarely for internal medicinal purposes.

OLEAGINOUS, something that partakes of the nature of oil, or out of which oil may be expressed.

OLECRANUM, or OLECRANON, in anatomy, the protuberance of the ulna, which prevents the joint of the elbow from being bent back beyond a certain length. See ANATOMY, n° 50.

OLEARIUS (Adam), minister to the duke of Holstein, and secretary to the embassy sent in 1633 to the great duke of Muscovy and to the king of Persia. He spent six years in this employment; and, on his return, published a relation of his journeys, with maps and figures, at Sleswic 1656, in folio. He wrote an *Abridgement of the chronicles of Holstein from* 1448 *to* 1663: and was appointed librarian to the duke of Holstein, in which capacity he probably died. He has the character of an able mathematician, an adept of music, and a good orientalist, especially in the Persian language.

OLEARIUS (Godfrey), son of Godfrey Olearius, D. D. superintendant of Halle in Saxony, was born there in 1639. He became professor of Greek at Leipsic; and shewed his abilities in that language by 52 exercitations on the dominical epistles, and upon those parts of the epistles in the New Testament which are read in the public exercises, and which among the Lutherans are the subject of part of their sermons. He discharged the most important posts in the university, and among other dignities was ten times rector of it. His learning and industry were displayed in 106 theological disputations, 61 in philosophy, some programmas upon difficult points, several speeches and theological counsels; which make two thick volumes: beside his *Moral Theology*, his *Introduction to Theology*, which treats of cases of conscience, and his *Hermeneutica Sacra*. He lived to a good old age, dying in 1713. His eldest son of his own name, was a man of genius and learning, a professor in the same university, who published several works, but died young of a consumption before his father.

OLERON, an island of France, on the coast of Aunis and Saintonge, about five miles from the continent. It is 12 miles in length, and five in breadth; and is very fertile, containing about 12,000 inhabitants, who are excellent seamen. It is defended by a castle, which is well fortified; and there is a lighthouse placed here for the direction of ships. It is 14 miles south-east of Rochelle. W. Long. 1. 26. N. Lat. 46. 10.

Sea-Laws of OLERON, certain laws relative to maritime affairs, made in the time of Richard I. when he was at the island of Oleron. These laws, being accounted the most excellent sea-laws in the world, are recorded in the black book of the admiralty. See *Selden's Mare Clausum.*

OLFACTORY-NERVES. See ANATOMY, n°400.

OLIBANUM, (FRANKINCENSE), in pharmacy, a dry resinous substance, brought to us in detached pieces, or drops, as it were, like those of mastic; but larger, and of a less pure and pellucid texture. This drug has received many different appellations, according to its different appearances: the single tears are called simply *olibanum*, or *thus;* when two are joined together, they have been called *thus masculum*, and when very large, *thus fœmininum:* sometimes four or five, about the bigness of filberds, are found adhering to a piece of the bark of the tree which they exsuded from; these have been named *thus corticosum:* the finer powder which rubs off from the tears in the carriage, *mica thuris;* and the coarser powder, *manna thuris*. This drug is not however in any of its states which is now called *thus* or *frankincense* in the shops. See the article THUS.

Olibanum consists of about equal parts of a gummy and resinous substance; the first soluble in water, the other in rectified spirit. With regard to its virtues, abundance have been attributed to it, particularly in disorders of the head and breast, in hæmoptoes, and in alvine and uterine fluxes: but its real effects in these cases are far from answering the promises of the recommenders. Riverius is said to have had large experience of the good effects of this drug in pleurisies, especially epidemic ones: he directs a scooped apple to be filled with a dram of olibanum, then covered and roasted under the ashes; this is to be taken for a dose, three ounces of carduus water after it, and the patient covered up warm in bed; in a short time, he says, either a plentiful sweat, or a gentle diarrhœa, ensues, which carry off the disease. Geoffroy informs us, that he has frequently made use of this medicine after venesection, with good success; but acknowledges that it has sometimes failed.

OLIGÆDRA, in natural history, the name of a genus of crystals composed of very few planes, as the name expresses. The bodies of this class are crystals of the imperfect kind; being composed of columns affixed irregularly to some solid body at one end, and the other terminated by a pyramid: but the column and pyramid being both pentangular, the whole consists only of ten planes, and not, as the common kind, of 12.

OLIGARCHY, a form of government, wherein the administration of affairs is confined to a few hands.

OLISIPO, (Pliny, Antonine, Inscriptions); a town of Lusitania, situate on the north side of the frith of the Tagus; of such antiquity, that Solinus thought it was built by Ulysses: and Mela, probably to favour this opinion, writes, according the common copies, *Ulyssipo;* both of them perhaps deceived by the similarity of sound. It was a municipium, with the surname *Felicitas Julia*, a privilege granted by the munificence

nificence of Auguftus, (Infcriptions, Pliny.) Now *Lifbon*, capital of Portugal, fituate on the north bank of the Tagus, diftant about ten miles from its mouth.

OLIO, in cookery, denotes a favoury difh compofed of a great variety of ingredients, chiefly ufed by the Spaniards.

OLIVE, in botany. See OLEA.

Plate CCI. fig. 3.

OLIVE-*Prefs*. In order to obtain the olive oil, the olives are firft bruifed in a rough trough, under a millftone, rolling perpendicularly over them; and when fufficiently mafhed, put into the maye, or trough, *m*, of an olive-prefs, where *aa* are the upright beams, or cheeks; *b*, the female, and *c*, the male fcrew; *f*, the board on which the fcrew preffes; *g*, a cubical piece of wood, called a *block*; *b*, the peel, a circular board, to be put under the block. By turning the fcrew, all the liquor is preffed out of the mafhed olives, and is called *virgin-oil*; after which, hot water being poured upon the remainder in the prefs, a coarfer oil is obtained. Olive-oil keeps only about a year, after which it degenerates.

OLIVE-*Colour*, a yellow mingled with black.

OLIVER (Ifaac), an excellent Englifh painter, born in 1556; eminent both for hiftory and portraits. Several fine miniatures of this mafter are to be feen in the collections of our nobility and gentry; fome of them portraits of himfelf. As he was a very good defigner, his drawings are finifhed to an extraordinary degree of perfection; many being copies after Parmegiano. Rubens and Vandyck painted James I. after a miniature of Oliver's, which is a fufficient teftimony of his merit. He died in 1617.

OLIVER (Peter), the fon and difciple of Ifaac Oliver, was born in 1601. He arrived at a degree of perfection in miniature portraits confeffedly fuperior to his father, or any of his cotemporaries; as he did not confine his fubjects to a head only. In the collections of Charles I. and James II. there were 13 hiftorical fubjects painted by this Oliver; of which feven are ftill preferved in the clofet of queen Caroline at Kenfington: and a capital painting of his wife is in the poffeffion of the duchefs of Portland. He died in 1660.

OLIVET, or *Mount of* OLIVES, (anc. geog.), a mount which lay a little without Jerufalem, on the eaft fide (Zechar. xiv.); feparated from it by a deep valley called *Kedron*, (Jofephus), or the valley of Jehofaphat; diftant about eight furlongs or a mile from Jerufalem, (Luke); five furlongs, (Jofephus); which may be underftood of the nearer part of the mount.

OLMUTZ, a town of Germany, in Moravia, with a bifhop's fee, and a famous univerfity. The public buildings are very handfome, particularly the Jefuits college. It is a populous, trading, and very ftrong place; and yet it was taken, with the whole garrifon, by the king of Pruffia in 1741. In July 1758, he befieged it again; and when he had almoft taken the place, he was obliged to raife the fiege, to go and meet the Ruffian army. It is feated on the river Morave. E. Long. 17. 35. N. Lat. 49. 30.

OLYMPIA, (anc. geog.), with the furname *Pifatis*, (Strabo); fo called from the territory of Pifa in Elis; defcribed by Strabo, "as the temple of Jupiter Olympius, before which ftands a grove of wild olivetrees, in which is the ftadium, or foot-courfe, fo called, becaufe the eighth part of a mile; and by which the Alpheus, coming down from Arcadia, runs." A temple and fhrine highly ennobled by gymnaftic exercifes; and diftinguifhed by a peculiar degree of veneration, and ftill more fo by the ftatue of Jupiter, the work of Phidias, (Mela): fituated between Offa and Olympius, mountains cognominal with thofe of Theffally, diftant 12 miles from Pylos; famous for games called the *Olympian*, celebrated the beginning of each fifth year, by which Greece computed time, (Pliny;) a period of four years complete being called an *Olympiad*. Olympia was anciently called *Pifa*, or Pifa ftood in its neighbourhood; and there Jupiter Olympius was worfhipped. Hiftorians take no notice of Pifa, though poets do, but only of Olympia: which is thought to have arifen, if it had ever any habitations, (fo as to become a town or village, befides the temple and place of exercife,) from the ruins of Pifa; deftroyed by the Eleans, according to Paufanias; who adds, that not a veftige either of the houfes or walls was to be feen, but a plantation of vines on the fpot where it ftood. Again, Olympia and Pifa are faid to have ftood on different fpots, but in each other's adjacency. The public edifices of Olympia were the temple of Jupiter, the gymnafium, the portico, the dwellings of the Athletæ, the ftadium or raifed caufeway, the Hippodromus or chariot-courfe, the barrier and goal. *Olympiacus*, (Virgil;) *Olympicus*, (Horace;) the epithets. Now called *Longinico*, in the Morea: E. Long. 22. 0. N. Lat. 37. 30.

OLYMPIAD, the fpace of four years, whereby the Greeks reckoned time.

OLYMPIC GAMES, were folemn games among the ancient Greeks, fo called from Olympian Jupiter, to whom they were dedicated; and by fome faid to be firft inftituted by Jupiter, after his victory over the fons of Titan; others afcribe their inftitution to Hercules, not the fon of Alcmena, but one of much greater antiquity; others to Pelops; and others to Hercules the fon of Alcmena. Thefe games were fo confiderable, that the Greeks made them their epocha, diftinguifhing their years by the return of the Olympic games.

The care and management of the Olympics belonged for the moft part to the Eleans; who, on that account, enjoyed their poffeffions without moleftation or fear of war or violence. They appointed a certain number of judges, who were to take care that thofe who offered themfelves as competitors fhould perform their preparatory exercifes; and thefe judges, during the folemnity, fat naked, having before them a crown of victory, formed of wild olive, which was prefented to whomfoever they adjudged it. Thofe who were conquerors were called *Olympionices*, and were loaded with honours by their countrymen. At thefe games women were not allowed to be prefent; and if any woman was found, during the folemnity, to have paffed the river Alpheus, fhe was to be thrown headlong from a rock.

OLYMPUS, the name of feveral mountains; one bounding Bithynia on the fouth. Another in the ifland of Cyprus, on whofe top was a temple of Venus, which women were not permitted either to enter or to fee, (Strabo.) A third Olympus of Galatia, (Livy.) A fourth, of Lycia, with a noble cognominal town, near

near the fea-coaft, (Strabo, Cicero); extinct in Pliny's time, there remaining only a citadel: the town was deftroyed by P. Servilius Ifauricus, (Florus); having been the retreat of pirates. From this mountain there was an extenfive profpect of Lycia, Pamphylia, and Pifidia, (Strabo.) A fifth Olympus of Myfia, (Ptolemy); thence furnamed *Olympena*, anciently *Minor;* one of the higheft mountains, and furnamed *Myfius*, (Theophraftus); fituate on the Propontis, and thence extending more inland. A fixth, on the north of Theffaly, or on the confines of Macedonia; famous for the fable of the giants, (Virgil, Horace, Seneca); reckoned the higheft in the whole world, and to exceed the flight of birds, (Apuleius); which is the reafon of its being called *heaven*, than which nothing is higher: the ferenity and calmnefs which reign there are celebrated by Homer, Lucan, and Claudian.

OMBRE, a celebrated game at cards, borrowed from the Spaniards, and played by two, by three, or by five perfons, but generally by three. When three play at this game, nine cards are dealt to each party; the whole ombre pack being only 40; becaufe the eights, nines, and tens are thrown out of the pack. There are two forts of counters for ftakes, the greater and the leffer; the laft having the fame proportion to the other, as a penny to a fhilling: of the greater counters each man ftakes one for the game; and one of the leffer for paffing, for the hand when eldeft, and for every card taken in. As to the order and value of the cards, the ace of fpades, called *fpadillo*, is always the higheft trump, in whatfoever fuit the trump be; the *manille*, or black-duce, is the fecond; and the *bafto*, or ace of clubs, is always the third: the next in order is the king, the queen, the knave, the feven, the fix, the five, four, and three. Of the black there are 11 trumps; of the red, 12. The leaft fmall cards of the red are always the beft, and the moft of the black; except the duce and red feven, both of which are called the *manilles*, and are always fecond when the red is a trump. The red ace, when a trump, enters into the fourth place, and is called *punto*, otherwife it is only called an *ace*. The three principal cards are called *matadores;* which have this privilege, that they are not obliged to attend an inferior trump when it leads; but for want of a fmall trump, the perfon may renounce trumps, and play any other card; and when thefe are all in the fame hand, the others pay three of the greater counters a-piece; and with thefe three for a foundation, he may count as many matadores as he has cards in an uninterrupted feries of trumps; for all which the others are to pay one counter a-piece. He who hath the firft hand is called *ombre*, and has his choice of playing the game, of naming the trump, and of taking in as many and as few cards as he pleafes; and after him the fecond, &c. But if he does not name the trump before he look on the cards he has taken in, any other may prevent him, by naming what trump he pleafes. He that has the firft hand, fhould neither take in, nor play, unlefs he has at leaft three fure tricks in his hand: for, as he wins the game who wins moft tricks, he that can win five of the nine has a fure game; which is alfo the cafe if he wins four, and can fo divide the tricks as that one perfon may win two, and the other three.

If a perfon plays without difcarding or changing any cards, this is called *playing fans prendre;* and if another wins more tricks than he, he is faid to win codille. The over-fights in the courfe of the game, are called *beafts*. And if the ombre wins all the nine tricks, it is called *winning the vole*.

In ombre by five, which many, on account of its not requiring fo clofe an attention, prefer to that by three, only eight cards a-piece are dealt; and five tricks muft be won, otherwife the ombre is beafted. Here, the perfon who undertakes the game, after naming the trump, calls a king to his affiftance; upon which the perfon in whofe hand the king is, without difcovering himfelf, is to affift him as a partner, and to fhare his fate. If, between both, they can make five tricks, the ombre wins two counters, and the auxiliary king only one; but when the counters are even, they divide them equally. If the ombre venture the game without calling in any king, this too is called *playing fans prendre;* in which cafe other four are all againft him, and he muft win five tricks alone, or be beafted. The reft is much the fame as by three.

Ombre *de foleil*, "Shadow of the fun," in heraldry, is when the fun is borne in armory, fo as that the eyes, nofe, and mouth, which at other times are reprefented, do not appear; and the colouring is thin, fo that the field can appear through it.

OMBRIA, the ancient name of a province of Italy, in the territory of the pope, now called *Spoletto* and *Perugia*.

OMBRO, or Lombro, a town of Italy, in the duchy of Tufcany, and territory of the Siennois, fituated near the Tufcan fea, a little fouth of the lake of Caftiglione, 45 miles fouth-weft of Sienna.

OMELET, or Amlet, a kind of pancake or fricaffee of eggs, with other ingredients, very ufual in Spain and France. It may be made as follows: the eggs being beaten, are to be feafoned with falt and pepper, and then fried in butter made boiling hot; this done, gravy is to be poured on, and the whole ftewed with chives and parfley fhred fmall: when one fide is fried enough, it is to be turned on the other.

OMEN, a certain accident and cafual occurrence, that was thought to prefage either good or evil. There were three forts of omens among the ancients: one was of things internal, or thofe which affected the perfons themfelves; the fecond, of things external, that only appeared to men, but did not make any impreffion on them; the third were ominous words. Of the firft fort were thofe fudden conflernations, called *panic fears*, that feized upon men without any vifible caufe, and were therefore imputed to the demons, efpecially the god Pan: of thefe panics there is frequent mention in hiftory. The fecond fort of omens were of fuch things as appeared to men, but were not contained in their own bodies: of thefe there were feveral forts; the beginning of things were thought to contain fomething ominous; it was thought a direful omen, when any thing unufual befel the temples, altars, or ftatues of the gods: under the head of external omens are to be placed thofe which offered themfelves in the way; fuch were the meeting of an eunuch, a black, a bitch with whelps, a fnake lying in the road, &c. Words were ominous, and, as they were good or bad, were believed to prefage accordingly

ingly.

OMENTUM, or Epiloon, the *Cawl*, in anatomy, a membranaceous part, usually furnished with a large quantity of fat; being placed under the peritonæum, and immediately above the intestines. See Anatomy, n° 351.

OMBROMETER, a machine to measure the quantity of rain that falls. We have the description and sign of one in Phil. Transf. n° 473. p. 12. It consists of a tin funnel, whose surface is an inch square, with a flat board, and a glass tube set into the middle of it in a groove. The rise of the water in the tube, whose capacity at different times must be measured and marked, shews the quentity of rain that has fallen.

OMOPHAGIA, an ancient Greek festival, in honour of Bacchus, firnamed *Omophagos*, *i. e.* eater of raw-flesh. This festival was observed in the same manner with the other festivals of Bacchus, in which they counterfeited madness; what was peculiar to it, was, that the worshippers used to eat the entrails of goats, raw and bloody, in imitation of the god, who was supposed to do the same thing.

OMPHALMO-mesenteric, in anatomy. All fœtuses are wrapped up in at least two coats or membranes; most of them have a third, called *allantoides*, or *urinary*.

Some, as the dog, cat, hare, &c. have a fourth, which has two blood-vessels, viz. a vein and an artery, called *omphalo-mesenterics*, because passing along the string to the navel, and terminating in the mesentery.

ON, (anc. geog.), a town of Egypt towards Arabia, to the south-east of Babylon, and of the eastern branch of the Nile. The prophet Jeremiah calls it the house or town of the sun, in the land of Egypt. The high-priest Onias built a temple here, held in great esteem by the Hellenists.

ONANIA, or Onanism, terms lately framed to denote the crime of self-pollution, mentioned in scripture to have been committed by Onan, and punished in him with death.

This practice, however common, hath among all nations been reckoned a very great crime. In scripture, besides the instance of Onan abovementioned, we find self-polluters termed *effeminate*, *unclean*, *filthy*, and *abominable*. Even the heathens, who had not the advantage of revelation, were of the same opinion, as appears from the following lines of Martial.

Hoc nihil esse putes! scelus est; mihi crede, sed ingens
Quantum vix animo concipis ipse tuo.

You think 'tis nothing! 'tis a crime, believe!
A crime so great you scarcely can conceive.

Dr Tissot has published a treatise on the pernicious effects of this shameful practice, which appears to be no less baneful to the mind than to the body. He begins with observing, that, by the continual waste of the human body, aliments are required for our support. These aliments, however, require certain preparations in the body itself; and when by any means we become so altered that these preparations cannot be effected, the best aliments then prove insufficient for the support of the body. Of all the causes by which this morbid alteration is brought on, none is more common than too copious evacuations; and of all evacuations, that of the semen is the most pernicious when carried to excess. It is also to be observed, that though excess in natural venery is productive of very dangerous disorders, yet an equal evacuation by self-pollution, which is an unnatural way, is productive of others still more to be dreaded. The consequences enumerated by Dr Tissot are as follow.

1. All the intellectual faculties are weakened; the memory fails; the ideas are confused, and the patient sometimes even falls into a slight degree of insanity. They are continually under a kind of inward restlessness, and feel a constant anguish. They are subject to giddiness; all the senses, especially those of seeing and hearing, grow weaker and weaker, and they are subject to frightful dreams.

2. The strength entirely fails, and the growth in young persons is considerably checked. Some are afflicted with almost continual watching, and others dose almost perpetually. Almost all of them become hypochondriacs or hysteric, and are afflicted with all the evils which attend these disorders. Some have been known to spit calcareous matter; and others are afflicted with coughs, slow fevers, and consumptions.

3. The patients are affected with the most acute pains in different parts of the body, as the head, breast, stomach, and intestines; while some complain of an obtuse sensation of pain all over the body, on the slightest impression.

4. There are not only to be seen pimples on the face, which are one of the most common symptoms; but even blotches, or suppurative pustules, appear on the face, nose, breast, and thighs; and sometimes fleshy excrescences arise on the forehead.

5. The organs of generation are also affected; and the semen is evacuated on the slightest irritation, even that of going to stool. Numbers are afflicted with an habitual gonorrhœa, which entirely destroys the vigour of the constitution, and the matter of it resembles a fetid sanies. Others are affected with painful priapisms, dysuries, stranguries, and heat of urine, with painful tumours in the testicles, penis, bladder, and spermatic cord.

6. The functions of the intestines are sometimes totally destroyed; and some patients complain of costiveness, others of diarrhœa, piles, and the running of a fœtid matter from the fundament.

With regard to the cure, the first step is to leave off those practices which have occasioned the disease: which our author asserts is no easy matter; as, according to him, the soul itself becomes polluted, and can dwell on no other idea; or if she does, the irritability of the parts of generation themselves quickly recal ideas of the same kind. This irritability is no doubt much more to be dreaded than any pollution the soul can have received; and by removing it, there will be no occasion for exhortations to discontinue the practice. The principal means for diminishing this irritability are, in the first place, to avoid all stimulating, acrid, and spiced meats. A low diet, however, is improper, because it would further reduce the body already too much emaciated. The food should therefore be nutritive, but plain, and should consist of flesh rather roasted than boiled, rich broths, &c. It is certain,

tain, however, that as these foods contribute to restore the strength of the body, the stimulus on the organs of generation will be proportionably increased, by the semen which is constantly secreted, and which will now be in larger quantity than even in healthy persons, owing to the great evacuations of it which have preceded. Some part of the semen is gradually absorbed by the lymphatics; in consequence of which, the remainder becomes thick, acrid, and very stimulating. To remedy this, exercise is to be used, and that not only for pleasure, but till it is attended with a very considerable degree of fatigue. The sleep also must be no more than is barely sufficient to repair the fatigues occasioned by the exercise, or other employment; for an excess in sleep is as bad as idleness or stimulating foods. Excess in wine or intoxicating liquors is also to be avoided; or rather such liquors ought never to be tasted, unless as a medicine to restore the exhausted spirits: and to all this ought to be joined the Peruvian bark, which hath this admirable property, that, with little or no stimulus, it restores the tone of the system, and invigorates the body in a manner incredible to those who have not observed its effects. If these directions are followed, the patient may almost certainly expect a recovery, provided any degree of vital strength remains; and those who desire a life of celibacy on a moral account, will find them much more effectual than all the vows of chastity they can make.

ONCA, or ONCE, in zoology. See FELIS.

ONEGA, a river and lake of the Russian empire, between Muscovite Carelia, the territory of Cargapol, and Swedish Carelia. It is 100 miles in length and 40 in breadth, having a communication with the lake Ladoga, and consequently with Petersburgh. The river has its source in Cargapol, and gives its name to a country full of woods.

ONEGLIA, a sea-port town of Italy, in the territory of Genoa, with the title of a principality; but it belongs to the king of Sardinia, as well as the province, which abounds in olive-trees, fruit and wine. It has often been taken and retaken in the wars of Italy; which is no wonder, as it is an open place. The French and Spaniards had possession of it in 1744, but were driven out by the Piedmontese; however, they returned next winter, and again made themselves masters of it. E. Long. 8. 1. N. Lat. 43. 55.

ONEIROCRITICA, the art of interpreting dreams; or a method of foretelling future events by means of dreams. See DREAM, DIVINATION, &c.—The word is formed from the Greek ονειρος, "dream," and κριτικη, of κρισις, "judgment."—Some call it *oneirocritica;* and derive it from ονειρος, and κρατεω, "I possess, I command."

It appears from several passages of scripture, that there was, under the Jewish dispensation, such a thing as foretelling future events by dreams; but then there was a particular gift, or revelation, required for that purpose.

Hence it has been inferred, that dreams are really significative, and do forebode something to come; and all that is wanting among us is the *oneirocritica*, or the art of knowing what: yet it is the opinion of many, that dreams are mere chimeras; bearing, indeed, some relation to what has passed, but none to what is to come.—As to the case of Joseph, it was possible for God, who knew all things, to discover to him what was in the womb of fate; and to introduce that, he might take the occasion of a dream.

ONEIROCRITICS, a title given to interpreters of dreams, or those who judge of events from the circumstances of dreams.

There is no great regard to be had to those Greek books called *oneirocritics;* nor do we know why the patriarch of Constantinople, and others, should amuse themselves with writing on so pitiful a subject.

Rigault has given us a collection of the Greek and Latin works of this kind; one attributed to Astrampsichus; another to Nicephorus, patriarch of Constantinople; to which are added the treatises of Artemidorus and Achmet.—But the books themselves are little else than reveries; a kind of waking dreams, to explain and account for sleeping ones.

The secret of oneirocriticism, according to them all, consists in the relation supposed to be between the dream, and the thing signified: but they are far from keeping to the relations of agreement and similitude; and frequently have recourse to others of dissimilitude, and contrariety.

ONESIÆ THERMÆ, (Strabo;) who calls them *excellent baths*, and *salutary waters*, at the foot of the Pyrenees in Aquitania. Near the river Aturus stands at this day the town Bagneres, famous for its waters, which appear to be the *Onesiæ* of Strabo; situate in the county of Bigorre in Gascony, near the river Adour.

ONIÆ OPPIDUM and *Templum*, (Josephus); so called from Onias, the high-priest of the Jews in Egypt; who built a temple in imitation of that at Jerusalem, by permission of the king of Egypt, on the spot where stood the temple of Diana Agrestis in Leontopolis: it was encompassed with a brick wall, and had a large tower like that at Jerusalem, (Josephus:) it was the metropolis of the Nomos Heliopolites, (Ptolemy;) because in Strabo's time Heliopolis was fallen to decay.

ONGLEE, in heraldry, an appellation given to the talons or claws of beasts or birds, when borne of a different colour from that of the body of the animal.

ONION. See CEPA.—Onions, leeks, and garlic, are all of the same genus; and in their recent state are are acrid, but harmless to the human body. When, by age or climate, this acrimony is too great, we do not use them as food. In Spain, the garlic being equally mild with the onion is used as common food. By the ordinary culinary preparation their acrimony is dissipated, and a remarkably mild substance remains, promising much nutriment, which those who can digest them raw will certainly obtain. Though sometimes shunned as food, yet they are on that account used in medicine, uniting the two qualities of pectorals, viz. on the account of their acrimony, being in their recent state expectorant; in their boiled state, on account of their mucilage, demulcent, provided the quantity taken be sufficient. Some of late, in this country, have found in leeks a somniferous quality; but this is not yet confirmed by a sufficient number of experiments.—Besides the three abovementioned, there are several

feveral others belonging to the fame tribe, which we ufe as condiment; but only the leek and onion as diet. In its recent ftate, the onion is the moft acrid; in its boiled ftate, the leek retains its acrimony moft tenacioufly. On account of this, and fome difference of texture, the onion is more eafily digefted, and more univerfally ufed, than the leek; being more eafily broke down, and more generally agreeable.

ONISCUS, in zoology, a genus of infects belonging to the order of aptera. It has 14 legs, briftly feelers, and an oval body. There are 15 fpecies; of which the moft remarkable are, 1. The entomon, or fea wood-loufe, is white; eyes black; convex above, beneath flat, margin acute: Antennæ 4: Four hind pair of legs largeft, hairy. Body of 7 fegments. Length $1\frac{1}{2}$ line. Found on the coaft. It accompanies the herring, and is an enemy well known to our fifhermen: thefe infects will frequently eat up a whole fifh while it hangs in the net.—2. Afellus, millepes, or wood-loufe, is oval; the tail obtufe, with 2 undivided briftles: Various as to colour: Length, 5 lines. Their ufe in medicine is well known.

ONKELOS, furnamed the *Profelyte*, a famous rabbi of the firft century, and the author of the Chaldee Targum on the Pentateuch. He flourifhed in the time of Jefus Chrift, according to the Jewifh writers; who all agree, that he was, at leaft in fome part of his life, cotemporary with Jonathan Ben Uzziel, author of the fecond Targum upon the prophets. Dean Prideaux thinks he was the elder of the two, for feveral reafons: the chief of which is the purity of the ftyle in his Targum, therein coming neareft to that part of Daniel and Ezra which is in Chaldee, and is the trueft ftandard of that language, and confequently is the moft ancient; fince that language, as well as others, was in a conftant flux, and continued deviating in every age from the original: nor does there feem to be any reafon why Jonathan Ben Uzziel, when he underftood his Targum, fhould pafs over the law, and begin with the prophets, but that he found Onkelos had done this work before him, and with a fuccefs which he could not exceed.

Azaries, the author of a book, intitled *Meor Enaim*, or the *Light of the Eyes*, tells us, that Onkelos was a profelyte in the time of Hillel and Samnai, and lived to fee Jonathan Ben Uzziel one of the prime fcholars of Hillel. Thefe three doctors flourifhed 12 years before Chrift, according to the chronology of Gauz; who adds, that Onkelos was cotemporary with Gamaliel the elder, St Paul's mafter, who was the grandfon of Hillel, who lived 28 years after Chrift, and did not die till 18 years before the deftruction of Jerufalem. However, the fame Gauz, by his calculation, places Onkelos 100 years after Chrift; and to adjuft his opinion with that of Azarias, extends the life of Onkelos to a great length. The Talmudifts tell us that he affifted at the funeral of Gamaliel, and was at a prodigious expence to make it moft magnificent. Dean Prideaux obferves, that the Targum of Onkelos is rather a verfion than a paraphrafe; fince it renders the Hebrew text word for word, and for the moft part accurately and exactly, and is by much the beft of all this fort: and therefore it has always been held in efteem among the Jews, much above all the other Targums; and being fet to the fame mufical notes with the Hebrew text, it is thereby made capable of being read in the fame tone with it in their public affemblies. From the excellency and accuracy and Onkelos's Targum, the dean alfo concludes him to have been a native Jew, fince, without being bred up from his birth in the Jewifh religion and learning, and long exercifed in all the rites and doctrines thereof, and being alfo thoroughly fkilled in both the Hebrew and Chaldee languages, as far as a native Jew could be, he can fcarce be thought thoroughly adequate to that work which he performed; and that the reprefenting him as a profelyte, feems to have proceeded from the error of taking him to have been the fame with Akilas, or Aquila, of Pontus, author of the Greek Targum or verfion of the prophets and Hagiographia, who was indeed a Jewifh profelyte.

ONKOTOMY, in furgery, the opening of a tumour or abfcefs. See SURGERY.

ONOMANCY, or rather ONOMAMANCY, a branch of divination, which foretells the good or bad fortune of a man, from the letters in his name. See the article DIVINATION.

From much the fame principle the young Romans toafted their miftreffes as often as there were letters in their names: hence Martial fays,

Nævia fex cyathis, feptem Juftina bibatur.

ONOMATOPOEIA, in grammar and rhetoric, a figure where words are formed to refemble the found made by the things fignified; as the buzz of bees, the cackling of hens, &c.

ONOSANDER, a Greek author and Platonic philofopher, who wrote Commentaries on Plato's politics, which are loft: but his name is particularly famous for a treatife intitled Λογος Στρατηγικος, "Of the duty and virtues of the general of an army;" which has been tranflated into Latin, Italian, Spanifh, and French. The time when he lived is not precifely known; but is imagined to be in the reign of the emperor Claudius.

ONTARIO, a lake of North America, in the country of the Iroquois, 180 miles in length and 60 in breadth. There are many rivers that run into it; and from it the great river St Lawrence proceeds. It communicates with lake Erie by a river 33 miles in length, in which is the remarkable cataract of NIAGARA.

ONTOLOGY. See METAPHYSICS, n° 1.

ONUPHRIUS PANVINUS, a learned Italian, of the order of hermits of St Auguftine, was born of a noble family at Verona, in 1529; and, being trained to literature, became fo indefatigable in his ftudies, that he fpent whole days and nights in reading the ancients: which made Manutius ftyle him *Helluo Antiquitatis*. His firft performance was A Chronicle of Popes and Cardinals, which was printed without his knowledge at Venice in 1557; and fome time after, more correctly by himfelf. He afterwards continued Platina's Lives of the Popes, from Sextus IV. to Pius V. and fubjoined annotations to the lives Platina had written. He alfo wrote four pieces upon Roman Antiquities, which are printed in Grævius's Collection. He died in his 39th year, in 1568.

ONYCOMANCY, or, as fome write it, ONYMANCY; a kind of divination by means of the nails of the fingers.——The word is formed from the Greek ονυξ, "nail," and μαντεια, "divination."

The ancient practice was to rub the nails of a youth with oil and foot, or wax; and to hold up the nails thus fmeared againft the fun.—Upon them were fuppofed to appear figures or characters, which fhewed the thing required.

ONYX, in natural hiftory, one of the femipellucid gems, with varioufly coloured zones, but none red; being compofed of cryftal, debafed by a fmall admixture of earth; and made up either of a number of flat plates, or of a feries of coats furrounding a central nucleus, and feparated from each other by veins of a different colour, refembling zones or belts.

We have four fpecies of this gem. 1. A bluifh-white one, with broad white zones. 2. A very pure onyx, with fnow-white veins. 3. The jafponyx, or horny-onyx, with green zones. 4. The brown onyx, with bluifh-white zones.

The ancients attributed wonderful properties to the onyx, and imagined that if worn on the finger it acted as a cardiac; they have alfo recommended it as an aftringent: but at prefent no regard is paid to it.

The word in the Greek language fignifies *nail;* the poets making this ftone to have been formed by the Parcæ, from a piece of Venus's nails, cut off by Cupid with one of his arrows.

OOST, a kiln for drying hops after they are picked from the ftalks.

OPACITY, in philofophy, a quality of bodies which renders them impervious to the rays of light.

OPAL, in natural hiftory, a fpecies of the chroaftaces genus of gems.

The opal is a gem of a very peculiar kind, and has been efteemed by many in all ages of very great value; though at prefent it is of lefs value, in proportion to its fize, than any of the finer gems. It is fofter than any other of the fine gems, and is difficult to polifh to any degree of nicety. It is found of various fhapes and fizes; its moft frequent bignefs is between that of a pea and a horfe-bean; but it is found as fmall as the head of a large pin, and has been feen of the fize of a large walnut. Its figure is very various and uncertain, but it is never found in a cryftalliform or columnar ftate; its moft ufual fhape is an irregular oblong one, convex above, flatted at bottom, and dented with various finuofities at its fides. It is often found among the loofe earth of mountains, fometimes on the fhores of rivers, and not unfrequently bedded in the coarfer kinds of jafper. It is found in Egypt, Arabia, fome parts of the Eaft Indies, and in many parts of Europe: thofe of Europe are principally from Bohemia, and are of a greenifh or greyifh colour; the colour of the other opals much refembles the fineft mother of pearl, its bafis feeming a bluifh or greyifh white, but with a property of reflecting all the colours of the rainbow, as turned differently to the light.

OPALIA, in antiquity, feafts celebrated at Rome in honour of the goddefs Ops. Varro fays they were held on the 19th of December, which was one of the days of the faturnalia: thefe two feafts were celebrated in the fame month, becaufe Saturn and Ops were hufband and wife: the vows offered to the goddefs were made fitting on the ground.

OPERA, a dramatic compofition fet to mufic, and fung on the ftage, accompanied with mufical inftruments, and enriched with magnificent dreffes, machines, and other decorations. See POETRY, ch. ii. and MUSIC, n° 26.

OPERATION, in general, the act of exerting or exercifing fome power or faculty, upon which an effect follows.

OPERATION, in furgery and medicine, denotes a methodical action of the hand on the human body, in order to re-eftablifh health.

OPHIDIUM, a genus of fifhes belonging to the order of apodes. The head is fomewhat naked; the teeth are in the jaws, palate, and fauces; there are feven rays in the gill-membranes; and the body is fhaped like a fword. There are two fpecies.

OPHIOGLOSSUM, ADDER'S-TONGUE; a genus of the order of filices, belonging to the cryptogamia clafs of plants. There are feven fpecies; of which the only remarkable one is the vulgatum, or common adder's-tongue, which is a native of feveral places of Britain, growing in meadows and moift paftures. The country-people make an ointment of the frefh leaves, and ufe it as a vulnerary to green wounds; which is a very ancient application, recommended by Matthiolus, Tragus, and others.

OPHIOMANCY, in antiquity, the art of making predictions from ferpents. Thus Calchas, on feeing a ferpent devour eight fparrows with their dam, foretold the duration of the fiege of Troy: and the feven coils of a ferpent that was feen on Anchifes's tomb, were interpreted to mean the feven years that Æneas wandered from place to place before he arrived at Latium.

OPHIORHIZA, in botany, a genus of the monogynia order, belonging to the pentandria clafs of plants. There are two fpecies; the moft remarkable of which is the Afiaticum, or true lignum colubrinum. The root of this is known in the Eaft Indies to be a fpecific againft the poifon of that moft dreadful animal called the *hooded ferpent*. There is a treatife in *Amœn. Acad.* tom. iv. upon this fubject, wherein the author Joh. And. Darelius undertakes, from the defcription of fuch authors as had feen it upon the fpot, to afcertain the plant from which the genuine root is taken. It appears in this account, that it had puzzled the European phyficians; and what had been fold in the fhops for it, is the root of a very different plant, and of a poifonous nature.

The true root is called *mungus*, for the following reafon.—There is a kind of weafel in the Eaft Indies, called *mungutia* by the natives, *mungo* by the Portuguefe, and *muncas* by the Dutch. This animal purfues the hooded ferpent, as the cat does the moufe with us. As foon as this ferpent appears, the weafel attacks him; and if fhe chances to be bit by him, fhe immediately runs to find a certain vegetable, upon eating which fhe returns, and renews the fight.—The Indians are of opinion that this plant is the mungos.

That celebrated traveller Kempfer, who kept one of thefe weafels tame, that eat with him, lived with him, and was his companion wherever he went, fays he faw one of thefe battles between her and the ferpent, but could not certainly find out what root the weafel looked out for. But whether the weafel firft difcovered this antidote or not, it is an infallible remedy

remedy againſt the bite of the hooded ſerpent. And this he undertakes to aſcertain.

OPHITES, in natural hiſtory, a ſort of variegated marble, of a duſky-green ground, ſprinkled with ſpots of a lighter green, otherwiſe called *ſerpentine*. See the article MARBLE.

OPHITES, in church-hiſtory, Chriſtian heretics, ſo called both from the veneration they had for the ſerpent that tempted Eve, and the worſhip they paid to a real ſerpent: they pretended that the ſerpent was Jeſus Chriſt, and that he taught men the knowledge of good and evil. They diſtinguiſhed between *Jeſus* and *Chriſt:* Jeſus, they ſaid, was born of the Virgin, but Chriſt came down from heaven to be united with him; Jeſus was crucified, but Chriſt had left him to return to heaven. They diſtinguiſhed the God of the Jews, whom they termed *Jaldabaoth*, from the ſupreme God: to the former they aſcribed the body, to the latter the ſoul of men. They had a live ſerpent, which they kept in a kind of cage; at certain times they opened the cage-door, and called the ſerpent: the animal came out, and, mounting upon the table, twined itſelf about ſome loaves of bread; this bread they broke and diſtributed it to the company, who all kiſſed the ſerpent: this they called their *Euchariſt*.

OPHIR, a country mentioned in ſcripture, from which Solomon had great quantities of gold brought home in ſhips which he ſent out for that purpoſe; but where to fix its ſituation is the great difficulty, authors running into various opinions on that head. Some have gone to the Weſt, others to the Eaſt Indies, and the eaſtern coaſts of Africa, in ſearch of it. The generality place Ophir in the Eaſt Indies: but where there, is the queſtion; many taking it for Taphrobana, now ſuppoſed to be Ceylon; others for Pegu, or for Sumatra; or for the Aurea Cherſoneſus, now Malacca: unleſs *Aurea Cherſoneſus* be, as many think, an appellative common to all countries producing gold. Kircher takes the term *Ophir* to be of Egyptian original, and to denote a great part of India: and, to obviate difficulties, perhaps it is beſt to take *Ophir* for India at large, without confining it to any particular country, not excluding even China and the Japaneſe iſlands.

OPHRYS, TWYBLADE; a genus of the diandria order, belonging to the gynandria claſs of plants. The ſpecies are numerous; but the moſt remarkable are the following.

1. The ovata, oval-leaved ophrys, or common twyblade, hath a bulbous, fibrated root; crowned by two oval, broad, obtuſe, veined, oppoſite leaves; an erect, ſucculent, green ſtalk, ſix or eight inches high, naked above, and terminated by a looſe ſpike of greeniſh flowers, having the lip of the nectarium bifid. The flowers of this ſpecies reſemble the figure of gnats. 2. The ſpiralis, ſpiral orchis, or triple ladies-treſſes, hath bulbous, oblong, aggregated roots; crowned by a cluſter of oval, pointed, ribbed leaves; erect ſimple ſtalks, half a foot high; terminated by long ſpikes of white odoriferous flowers, hanging to one ſide, having the lip of the nectarium entire, and crenated. 3. The nidus-avis, or bird's-neſt, hath a bulboſe, fibrated, cluſtered root; upright, thick, ſucculent ſtalks, a foot high, ſheathed by the leaves, and terminated by looſe ſpikes of pale-brown flowers; having the lip of the nectarium bifid. 4. The anthropophora, man-ſhaped ophrys, or man-orchis, hath a roundiſh bulboſe root, crowned with three or four oblong leaves; upright thick ſtalks, riſing a foot and a half high; adorned with narrow leaves, and terminated by looſe ſpikes of greeniſh flowers, repreſenting the figure of a naked man; the lip of the nectarium linear tripartite, with the middle ſegment longeſt and bifid. There is a variety with browniſh flowers tinged with green. 5. The inſectifera, or inſect-orchis, hath two roundiſh bulbous roots, crowned with oblong leaves; erect leafy ſtalks, from ſix to 10 or 12 inches high, terminated by ſpikes of inſect-ſhaped greeniſh flowers, having the lip of the nectarium almoſt five-lobed. This wonderful ſpecies exhibit flowers in different varieties, that repreſent ſingular figures of flies, bees, and other inſects; and are of different colours in the varieties. 6. The monorchis, or muſky ophrys, hath a roundiſh bulboſe root; crowned with three or four oblong leaves; an erect naked ſtalk, ſix inches high; terminated by a looſe ſpike of yellowiſh, muſky-ſcented flowers.

All theſe ſix ſpecies of ophrys flower in ſummer, at different times in different ſorts, from May until July; and in moſt of the ſorts exhibit a ſingularly curious appearance. The plants are all perennial in root, which are of the bulbous fleſhy kind, from which the flower-ſtalks riſe annually in ſpring, and decay in autumn; at which period is the proper time for removing the roots from one place to another. They all grow wild in Britain, &c.; are reſidents of woods, bogs, marſhy grounds, ſterile paſtures, chalky ſoils, and the like places, where they flouriſh and diſplay their ſingular flowers in great abundance, from which places they are introduced into gardens for variety; and having procured ſome plants at the proper ſeaſon, and planted them in ſoils and ſituations ſomewhat ſimilar to that where they naturally grow, the roots will abide for ſeveral years, and flower annually.

As to their propagation, it may be tried by ſeed in a ſhady border, as ſoon as it is ripe; likewiſe by off-ſets from the root, though they multiply ſparingly in gardens: however, roots of ſome ſtanding may be examined at the proper ſeaſon, and any off-ſets ſeparated and planted in the proper places.

OPHTHALMOSCOPY, a branch of phyſiognomy, which deduces the knowledge of a man's temper and manner from the appearance of his eyes.

OPHTHALMIA, in medicine, an inflammation of the membranes which inveſt the eye; eſpecially of the adnata, or albugineous coat. See MEDICINE, n° 283.

OPIATES, medicines of a thicker conſiſtence than a ſyrup, prepared with opium ſcarcely fluid. They conſiſt of various ingredients, made up with honey or ſyrup; and are to be uſed for a long time either for purgative, alterative, or corroborative intentions.

The word *opiate* is alſo uſed, in general, for any medicine given with an intention to procure ſleep, whether in the form of electuaries, drops, or pills.

OPITS, or OPITIUS (Martin), a celebrated German poet, born at Breſlaw in 1507. He acquired great fame by his Latin, and more by his German poems; and, retiring to Dantzic, wrote a hiſtory of the ancient

ancient Daci: he died of the plague in 1639.

Opits (Henry), a learned Lutheran divine, born at Altenburg in Misnia in 1642. He was professor of theology and of the oriental languages at Kiel, where he acquired great reputation by a variety of excellent works concerning oriental literature and Hebrew antiquities. He died in 1712.

OPIUM, in the materia medica, is an inspissated juice, partly of the resinous and partly of the gummy kind, brought to us in cakes from eight ounces to a pound weight. It is very heavy, of a dense texture, and not perfectly dry; but, in general, easily receives an impression from the finger: its colour is a brownish yellow, so very dark and dusky that at first it appears black: it has a dead and faint smell, and its taste is very bitter and acrid. It is to be chosen moderately firm, and not too soft; its smell and taste should be very strong, and care is to be taken that there be no dirty or stony matter in it.

Opium is the juice of the papaver album, or white poppy, with which the fields of Asia Minor are in many places sown, as ours are with corn. When the heads are near ripening, they wound them with an instrument that has five edges, which on being stuck into the head makes at once five long cuts in it; and from these wounds the opium flows, and is next day taken off by a person who goes round the field, and put up in a vessel which he carries fastened to his girdle; at the same time that this opium is collected, the opposite side of the poppy-head is wounded, and the opium collected from it the next day. They distinguish, however, the produce of the first wounds from that of the succeeding ones; for the first juice afforded by the plant is greatly superior to what is obtained afterwards. After they have collected the opium, they moisten it with a small quantity of water or honey, and work it a long time upon a flat, hard, and smooth board, with a thick and strong instrument of the same wood, till it becomes of the consistence of pitch; and then work it up with their hands, and form it into cakes or rolls for sale.

Opium at present is in great esteem, and is one of the most valuable of all the simple medicines. Applied externally, it is emollient, relaxing, and discutient, and greatly promotes suppuration: if long kept upon the skin, it takes off the hair, and always occasions an itching in it; sometimes is exulcerates it, and raises little blisters, if applied to a tender part. Sometimes, on external application, it allays pain, and even occasions sleep: but it must by no means be applied to the head, especially to the sutures of the skull; for it has been known to have the most terrible effects in this application, and even to bring on death itself. Opium, taken internally, removes melancholy, eases pain, and disposes to sleep; in many cases removes hæmorrhages, and provokes sweating. A moderate dose is commonly under a grain; though, according to the circumstances, two grains, or even three, may be within the limits of this denomination: but custom will make people bear a dram or more; though in this case nature is vitiated, and nothing is to be hence judged in regard to others. If given dissolved, it operates in half an hour; if in a solid form, as in pills, or the like, it is sometimes an hour and a half. Its first effect, in this case, is the making the patient cheerful, as if he had drank moderately of wine, and at the same time bold and above the fear of danger; for which reason the Turks always take it when they are going to battle. A very immoderate dose brings on a sort of drunkenness, much like that occasioned by an immoderate quantity of strong liquors; cheerfulness and loud laughter at first, than a relaxation of the limbs, a loss of memory, and lightheadedness; then vertigoes, dimness of the eyes, with a laxity of the cornea and a dilatation of the pupils, a slowness of the the pulse, redness of face, relaxation of the under-jaws, swelling of the lips, difficulty of breathing, painful erection of the penis, convulsions, cold sweat, and finally death. Those who escape are usually relieved by a great number of stools, or profuse sweats.

OPOBALSAMUM, in the materia medica. Opobalsam, or balm of Gilead; a resinous juice, obtained from an evergreen tree, or shrub, growing spontaneously in Arabia. The best sort, which naturally exsudes from the plant, is scarce known to Europe; and the inferior kinds, said to be extracted by lightly boiling the leaves and branches in water, are very rarely seen among us. The true opobalsam, according to Alpinus, is at first turbid and white; of a very strong pungent smell, like that of turpentine, but much sweeter; and of a bitter, acrid, astringent taste; upon being kept for some times it becomes thin, limpid, light, of a greenish hue; then of a gold yellow; and at length of the colour of honey: after this it grows thick like turpentine, and loses much of its fragrance. This balsam is of great esteem in the eastern countries, both as a medicine, and as an odoriferous unguent and cosmetic. Its great scarcity has prevented its coming into use among us; in the mithridate and theriaca, which it is directed as an ingredient in, the London college allows the expressed oil of nutmegs as a succedaneum to it.

OPOPANAX, in the materia medica, is a gum resin of a tolerably firm texture, usually brought to us in loose granules or drops, and sometimes in large masses, formed of a number of these connected by a quantity of matter of the same kind; but these are usually loaded with extraneous matter, and are greatly inferior to the pure loose kind. The drops or granules of the fine opopanax, are on the outside of a brownish red colour, and of a dusky yellowish or whitish colour within: they are of a somewhat unctuous appearance, smooth on the surface; and are to be chosen in clear pieces, of a strong smell and acrid taste.

Opopanax is attenuating and discutient, and is gently purgative; it dispels flatulencies, and is good in asthmas, in inveterate coughs, and in disorders of the head and nerves. It also promotes the menses, and is good against all obstructions of the viscera.

OPOSSUM, in zoology. See Didelphis.

OPPIANUS, a poet and grammarian of Anazarba in Cilicia, in the second century. He composed a poem of hunting, and another of fishing, for which Antoninus Caracalla gave him as many golden crowns as their were verses in his poems; they were called hence *Oppian's golden verses*. He died in the 30th year of his age.

OPPILATION, in medicine, the act of obstructing or stopping up the passages of the body, by redundant

dundant or peccant humours. This word is chiefly uſed for obſtructions in the lower belly.

OPTATIVE MOOD, in grammar, that which ſerves to expreſs an ardent deſire or wiſh for ſomething.

In moſt languages, except the Greek, the optative is only expreſſed by prefixing to the ſubjunctive an adverb of wiſhing; as *utinam*, in Latin; *plut a Dieu*, in French; and *would to God*, in Engliſh.

OPTIC ANGLE, the angle which the optic axes of both eyes make with one another, as they tend to meet at ſome diſtance before the eyes.

OPTIC *Axis*, the axis of the eye, or a line going through the middle of the pupil, and the centre of the eye.

OPTICS;

THAT ſcience which treats of element of the light, and the various phenomena of viſion.

HISTORY.

§ 1. *Diſcoveries concerning the Light.*

THESE are enumerated under the article LIGHT ſo fully, that there is little room for any further addition here. The nature of that ſubtile element is indeed very little known as yet, notwithſtanding all the endeavours of philoſophers; and whatever ſide is taken with regard to it, whether we ſuppoſe it to conſiſt of an infinity of ſmall particles propagated by a repulſive power from the luminous body, or whether we ſuppoſe it to conſiſt in the vibrations of a ſubtile fluid, there are prodigious difficulties, almoſt, if not totally inſuperable, which will attend the explanation of its phenomena. In many parts of this work the identity of light and of the electric fluid is aſſerted: this, however, doth not in the leaſt interfere with the phenomena of optics; all of which are guided by the ſame invariable laws, whether we ſuppoſe light to be a vibration of that fluid, or any thing elſe. We ſhall therefore proceed to,

1 Great difficulties attend the explanation of the phenomena of light.

§ 2. *Diſcoveries concerning the Refraction of Light.*

2 Refraction known to the ancients.

WE find that the ancients, though they made very few optical experiments, nevertheleſs knew, that when light paſſed through mediums of different denſities, it did not move forward in a ſtraight line, but was bent, or *refracted*, out of its courſe. This was probably ſuggeſted to them by the appearance of a ſtraight ſtick partly immerſed in water: and we find many queſtions concerning this and other optical appearances in Ariſtotle; to which, however, his anſwers are inſignificant. Archimedes is even ſaid to have written a treatiſe concerning the appearance of a ring or circle under water, and therefore could not have been ignorant of the common phenomena of refraction. But the ancients were not only acquainted with theſe more ordinary appearances of refraction, but knew alſo the production of colours by refracted light. Seneca ſays, that if the light of the ſun ſhines through an angular piece of glaſs, it will ſhew all the colours of the rainbow. Theſe colours, however, he ſays are falſe, ſuch as are ſeen in a pigeon's neck when it changes its poſition; and of the ſame nature he ſays is a ſpeculum, which, without having any colour of its own, aſſumes that of any other body. It appears alſo, that the ancients were not unacquainted with the magnifying power of glaſs globes filled with water, though they do not ſeem to have known any thing of the reaſon of this power; and the ancient engravers are ſuppoſed to have made uſe of a glaſs globe filled with water to magnify their figures, and thereby to work to more advantage. That the power of tranſparent bodies of a ſpherical form in magnifying or burning was not wholly unknown to the ancients, is farther probable from certain gems preſerved in the cabinets of the curious, which are ſuppoſed to have belonged to the Druids. They are made of rock-cryſtal of various forms, amongſt which are found ſome that are lenticular and others that are ſpherical: and though they are not ſufficiently wrought to perform their office as well as they might have done if they had been more judiciouſly executed, yet it is hardly poſſible that their effect, in magnifying at leaſt, could have eſcaped the notice of thoſe who had often occaſion to handle them; if indeed, in the ſpherical or lenticular form, they were not purpoſely intended for the purpoſes of burning. One of theſe, of the ſpherical kind, of about an inch and a half diameter, is preſerved among the foſſils given to the univerſity of Cambridge by Dr Woodward.

3 And the magnifying power of glaſs-globes.

4 Refraction firſt treated of by Ptolemy.

The firſt treatiſe of any note written on the ſubject of optics, was by the celebrated aſtronomer Claudius Ptolomæus, who lived about the middle of the ſecond century. The treatiſe is loſt; but from the accounts of others we find that he treated of aſtronomical refractions. Though refraction in general had been obſerved very early, it is poſſible that it might not have occurred to any philoſophers much before his time, that the light of the ſun, moon, and ſtars muſt undergo a ſimilar refraction, in conſequence of falling obliquely upon the groſs atmoſphere that ſurrounds the earth; and that they muſt, by that means, be turned out of their rectilinear courſe, ſo as to cauſe thoſe luminaries to appear higher in the heavens than they would otherwiſe do. The firſt aſtronomers were not aware that the intervals between ſtars appear leſs near the horizon than in the meridian; and, on this account, they muſt have been much embarraſſed in their obſervations. But it is evident that Ptolemy was aware of this circumſtance, by the caution that he gives to allow ſomething for it, upon every recourſe to ancient obſervations.

2 His hypotheſis concerning the horizontal ſun and moon.

This philoſopher alſo advances a very ſenſible hypotheſis to account for the remarkably greater apparent ſize of the ſun and moon when ſeen near the horizon. The mind, he ſays, judges of the ſize of objects by means of a pre-conceived idea of their diſtance from us: and this diſtance is fancied to be greater when a number of objects are interpoſed between the eye and the body we are viewing; which is the caſe when we ſee the heavenly bodies near the horizon. In his Almageſt, however, he aſcribes this appearance to a refraction

fraction of the rays by vapours, which actually enlarge the angle under which the luminaries appear; juſt as the angle is enlarged by which an object is ſeen from under water.

6 Diſcoveries of Alhazen.

In the 12th century, the nature of refraction was largely conſidered by Alhazen an Arabian writer; in ſo much that, having made experiments upon it at the common ſurface between air and water, air and glaſs, water and glaſs or cryſtal; and, being prepoſſeſſed with the ancient opinion of cryſtalline orbs in the regions above the atmoſphere, he even ſuſpected a refraction there alſo, and fancied he could prove it by aſtronomical obſervations. This author deduces from hence ſeveral properties of atmoſpherical refraction, as that it increaſes the altitudes of all objects in the heavens; and he firſt advanced, that the ſtars are ſometimes ſeen above the horizon by means of refraction, when they are really below it. This obſervation was confirmed by Vitellio, B. Waltherus, and eſpecially by the excellent obſervations of Tycho Brahe. Alhazen obſerved, that refraction contracts the diameters and diſtances of the heavenly bodies, and that it is the cauſe of the twinkling of the ſtars. But we do not find that either he, or his follower Vitellio, knew any thing of its juſt quantity. Indeed it is too ſmall to be determined except by very accurate inſtruments, and therefore we hear little more of it till about the year 1500; at which time great attention was paid to it by Bernard Walther, Mæſtlin, and others, but chiefly by Tycho Brahe.

Alhazen ſuppoſed that the refraction of the atmoſphere did not depend upon the vapours in it, as was probably the opinion of philoſophers before his time, but on the different tranſparency; by which, as Montucla conjectures, he meant the denſity of the groſs air contiguous to the earth, and the ether or ſubtile air that lies beyond it. In examining the effects of refraction, he endeavours to prove that it is ſo far from being the cauſe of the heavenly bodies appearing larger near the horizon, that it would make them appear leſs; two ſtars, he ſays, appearing nearer together in the horizon, than near the meridian. This phenomenon he ranks among optical deceptions. We judge of diſtance, he ſays, by comparing the angle under which objects appear, with their ſuppoſed diſtance; ſo that if theſe angles be nearly equal, and the diſtance of one object be conceived greater than that of the other, it will be imagined to be larger. And the ſky near the horizon he ſays is always imagined to be further from us than any other part of the concave ſurface. Roger Bacon aſcribes this account of the horizontal moon to Ptolemy; and as ſuch it is examined, and objected to by B. Porta.

In the writings of this philoſopher we find the firſt diſtinct account of the magnifying power of glaſſes; and it is not improbable, that what he wrote upon this ſubject gave riſe to that moſt uſeful invention of ſpectacles. For he ſays, that if an object be applied cloſe to the baſe of the larger ſegment of a ſphere of glaſs, it will appear magnified. He alſo treats of the appearance of an object through a globe, and ſays that he was the firſt who obſerved the refraction of rays into it.

7 Of Vitellio.

In 1270, Vitellio, a native of Poland, publiſhed a treatiſe of optics, containing all that was valuable in Alhazen, and digeſted in a much more intelligible and methodical manner. He obſerves, that light is always loſt by refraction, in conſequence of which the objects ſeen by refracted light always appear leſs luminous; but he does not pretend to eſtimate the quantity of this loſs. He reduced into a table the reſult of his experiments on the refractive powers of air, water, and glaſs, correſponding to different angles of incidence. In his account of the horizontal moon he agrees exactly with Alhazen; obſerving, that in the horizon ſhe ſeems to touch the earth, and appears much more diſtant from us than in the zenith, on account of the intermediate ſpace containing a greater variety of objects upon the viſible ſurface of the earth. He aſcribes the twinkling of the ſtars to the motion of the air in which the light is refracted; and to illuſtrate this hypotheſis, he obſerves, that they twinkle ſtill more when viewed in water put in motion. He alſo ſhews, that refraction is neceſſary as well as reflection, to form the rainbow; becauſe the body which the rays fall upon is a tranſparent ſubſtance, at the ſurface of which one part of the light is always reflected and another refracted. But he ſeems to conſider refraction as ſerving only to condenſe the light, and thereby enabling it to make a ſtronger impreſſion upon the eye. This writer alſo makes ſome ingenious attempts to explain refraction, or to aſcertain the law of it. He alſo conſiders the foci of glaſs ſpheres, and the apparent ſize of objects ſeen through them; though upon theſe ſubjects he is not at all exact. It is ſufficient indeed to ſhew the ſtate of knowledge, or rather of ignorance, at that time, to obſerve, that both Vitellio, and his maſter Alhazen, endeavour to account for objects appearing larger when they are ſeen under water by the circular figure of its ſurface; ſince, being fluid, it conforms to the figure of the earth.

8 Of Roger Bacon.

Cotemporary with Vitellio was Roger Bacon, a man of very extenſive genius, and who wrote upon almoſt every branch of ſcience; yet he does not ſeem to have made any conſiderable advances beyond what Alhazen had done before him. Even ſome of the wildeſt and moſt abſurd of the opinions of the ancients have had the ſanction of his authority. He does not heſitate to aſſent to an opinion adopted by many of the ancients, and indeed by moſt philoſophers till his time, that viſual rays proceed from the eye; giving this reaſon for it, that every thing in nature is qualified to diſcharge its proper functions by its own powers, in the ſame manner as the ſun and other celeſtial bodies. In his *Specula Mathematica*, he added ſome obſervations on the refraction of the light of the ſtars; the apparent ſize of objects; the extraordinary ſize of the ſun and moon in the horizon: but in all this he is not very exact, and advances but little. In his *Opus Majus* he demonſtrates, that if a tranſparent body interpoſed between the eye and an object, be convex towards the eye, the object will appear magnified. This obſervation, however, he certainly had from Alhazen; the only difference between them is, that Bacon prefers the ſmaller ſegment of a ſphere, and Alhazen the larger, in which the latter certainly was right.

9 Of Maurolycus.

From this time, to that of the revival of learning in Europe, we have no farther treatiſe on the ſubject of refraction, or indeed on any other part of optics. One of the firſt who diſtinguiſhed himſelf in this way was, Maurolycus teacher of mathematics at Meſſina. In a treatiſe

treatife, *De Lumine et Uumbra*, publifhed in 1575, he demonftrates that the cryftalline humour of the eye is a lens that collects the rays of light iffuing from the objects, and throws them upon the retina where is the focus of each pencil. From this principle he difcovered the reafon why fome people were fhort-fighted and others long-fighted; and why the former are relieved by concave, and the others by convex, glaffes.

10 Difcoveries of B. Porta.

About the fame time that Maurolycus made fuch advances towards the difcovery of the nature of vifion, Joannes Baptifta Porta of Naples difcovered the *camera obfcura*, which throws ftill more light on the fame fubject. His houfe was conftantly reforted to by all the ingenious perfons at Naples, whom he formed into what he called *an academy of fecrets*; each member being obliged to contribute fomething that was not generally known, and might be ufeful. By this means he was furnifhed with materials for his *Magia Naturalis*, which contains his account of the *camera obfcura*, and the firft edition of which was publifhed, as he informs us, when he was not quite 15 years old. He alfo gave the firft hint of the magic lantern; which Kircher afterwards followed and improved. His experiments with the *camera obfcura* convinced him, that vifion is performed by the intromiffion of fomething into the eye, and not by vifual rays proceeding from the eye as had been formerly imagined; and he was the firft who fully fatisfied himfelf and others upon this fubject. Indeed the refemblance between experiments with the *camera obfcura* and the manner in which vifion is performed in the eye, was too ftriking to efcape the obfervation of a lefs ingenious perfon. But when he fays that the eye is a *camera obfcura*, and the pupil the hole in the window-fhutter, he was fo far miftaken as to fuppofe that it was the cryftalline humour that correfponds to the wall which receives the images; nor was it difcovered till the year 1604, that this office is performed by the retina. He makes a variety of juft obfervations concerning vifion; and particularly explains feveral cafes in which we imagine things to be without the eye, when the appearances are occafioned by fome affection of the eye itfelf, or fome motion within the eye. He obferves alfo, that, in certain circumftances, vifion will be affifted by convex or concave glaffes; and he feems alfo to have made fome fmall advances towards the difcovery of telefcopes. He takes notice, that a round and flat furface plunged into water, will appear hollow as well as magnified to an eye perpendicularly over it; and he very well explains by a figure, the manner in which it is done.

11 The law of refraction difcovered.

All this time, however, the great problem concerning the meafuring of refractions had remained unfolved. Alhazen and Vitellio, indeed, had attempted it; but failed, by attempting to meafure the angle itfelf, inftead of its fine. At laft, however, it was difcovered by Snellius, profeffor of mathematics at Leyden. This philofopher, however, did not perfectly underftand his own difcovery, nor did he live to publifh any account of it himfelf. It was afterwards explained by profeffor Hortenfius both publicly and privately, before it appeared in the writings of Defcartes, who publifhed it under a different form, without making any acknowledgement of his obligations to Snellius, whofe papers Huygens affures us, from his own knowledge, Defcartes had feen.

12 Opinions of Defcartes and Leibnitz on this fubject.

It does not appear that, before Defcartes, any perfon attempted to explain the caufe of refraction; which he undertook to do by the refolution of forces, on the principles of mechanics. In confequence of this, he was obliged to fuppofe that light paffes with more eafe through a denfe medium, than through a rare one. The truth of this explanation was firft queftioned by M. Fermat, counfellor to the parliament of Thouloufe, and an able mathematician. He afferted, contrary to the opinion of Defcartes, that light fuffers more refiftance in water than air, and more in glafs than in water; and he maintained, that the refiftance of different mediums with refpect to light is in proportion to their denfities. M. Leibnitz adopted the fame general idea; and thefe gentlemen argued upon the fubject in the following manner.

Nature, fay they, accomplifhes her ends by the fhorteft methods. Light therefore ought to pafs from one point to another, either by the fhorteft road, or that in which the leaft time is required. But it is plain that the line in which light paffes, when it falls obliquely upon a denfer medium, is not the moft direct or the fhorteft; fo that it muft be that in which the leaft time is fpent. And whereas it is demoftrable, that light falling obliquely upon a denfer medium (in order to take up the leaft time poffible in paffing from a point in one medium to a point in the other) muft be refracted in fuch a manner, that the fines of the angles of incidence and refraction muft be to one another, as the different facilities with which light is tranfmitted in thofe mediums; it follows, that fince light approaches the perpendicular when it paffes obliquely from air into water, fo that the fine of the angle of refraction is lefs than that of the angle of incidence, the facility with which water fuffers light to pafs through it is lefs than that of the air; fo that light meets with more refiftance in water than air.

13 Difcoveries concerning the refraction of different fubftances.

Arguments of this kind could not give fatisfaction; and a little time fhewed the fallacy of the hypothefis. At a meeting of the Royal Society, Aug. 31. 1664. an experiment for meafuring the refraction of common water was made with a new inftrument which they had prepared for that purpofe; and, the angle of incidence being 40 degrees, that of refraction was found to be 30. About this time alfo we find the firft mention of mediums not refracting the light in an exact proportion to their denfities. For Mr Boyle, in a letter to Mr Oldenburgh, dated Nov. 3. 1664, obferves, that in fpirit-of-wine, the proportion of the fines of the angles of incidence to the fines of the angles of refraction was nearly the fame, viz. as 4 to 3; and that, as fpirit-of-wine occafions a greater refraction than common water, fo oil of turpentine, which is lighter than fpirit-of-wine, produces not only a greater refraction than common water, but a much greater than falt water. And at a meeting held Nov. 9. the fame year, Dr Hooke (who had been ordered to profecute the experiment) brought in an account of one that he had made with pure and clear fallad oil, which was found to have produced a much greater refraction than any liquor which he had then tried; the angle of refraction that anfwered to an angle of incidence of 30° being found no lefs than 40° 30′, and the angle of refraction that anfwered to an angle of incidence of 20° being 29° 47′.—M. de la Hire alfo made

made feveral experiments to afcertain the refractive power of oil with refpect to that of water and air, and found the fine of the angle of incidence to that of refraction to be as 60 to 42; which, he obferves, is a little nearer to that of glafs than to that of water, though oil is much lighter than water, and glafs much heavier.

The members of the Royal Society finding that the refraction of falt water exceeded that of frefh, purfued the experiment farther with folutions of vitriol, faltpetre, and alum, in water; when they found the refraction of the folution of vitriol and faltpetre a little more, but that of alum a little lefs, than common water.

Dr Hooke made an experiment before the Royal Society, Feb. 11. 1663, which clearly proves that ice refracts the light lefs than water; which he took to be a good argument that the lightnefs of ice, which caufes it to fwim in water, is not caufed only by the fmall bubbles which are vifible in it, but that it arifes from the uniform conftitution or general texture of the whole mafs. M. de la Hire alfo took a good deal of pains to determine whether, as was then the common opinion, the refractive power of ice and water were the fame; and he found, as Dr Hooke had done before, that ice refracts lefs than water.

By a moft accurate and elaborate experiment made in the year 1698, in which a ray of light was tranfmitted through a Torricellian vacuum, Mr Lowthorp found, that the refractive power of air is to that of water as 36 to 34,400. He concludes his account of the experiment with obferving, that the refractive power of bodies is not proportioned to the denfity, at leaft not to the gravity, of the refracting medium. For the refractive power of glafs to that of water, is as 55 to 34, whereas its gravity is as 87 to 34; that is, the fquares of their refractive powers are very nearly as their refpective gravities. And there are fome fluids, which, though they are lighter than water, yet have a greater power of refraction. Thus the refractive power of fpirit-of-wine, according to Dr Hooke's experiment, is to that of water as 36 to 33, and its gravity reciprocally as 33 to 36, or $36\frac{1}{2}$. But the refractive powers of air and water feem to obferve the fimple proportion of their gravities directly. And if this fhould be confirmed by fucceeding experiments, it is probable, he fays, that the refractive powers of the atmofphere are every-where, and at all heights above the earth, proportioned to its denfity and expanfion: and then it would be no difficult matter to trace the light through it, fo as to terminate the fhadow of the earth; and, together with proper expedients for meafuring the quantity of light illuminating an opaque body, to examine at what diftances the moon muft be from the earth to fuffer eclipfes of the obferved durations.

Caffini the younger happened to be prefent when Mr Lowthorp made the abovementioned experiment before the Royal Society; and upon his return home, having made a report of it to the members of the Royal Academy of Sciences, thofe gentlemen endeavoured to repeat the experiment in 1700; but they did not fucceed.—For, as they faid, beams of light paffed through the vacuum without fuffering any refraction. The Royal fociety being informed of this, were defirous that it might be put paft difpute, by repeated and well-attefted trials; and ordered Mr Haukfbee to make an inftrument for the purpofe, by the direction of Dr Halley. It confifted of a ftrong brafs prifm, two fides of which had fockets to receive two plane glaffes, whereby the air in the prifm might either be exhaufted or condenfed. The prifm had alfo a mercurial gage fixed to it, to difcover the denfity of the contained air; and was contrived to turn upon its axis, in order to make the refractions equal on each fide when it was fixed to the end of a telefcope. The refracting angle was near 64°; and the length of the telefcope was about 10 feet, having a fine hair in its focus. The event of this accurate experiment was as follows:

Having chofen a proper and very diftinct erect object, whofe diftance was 2588 feet, June 15. O. S. 1708, in the morning, the barometer being then at 29. $7\frac{1}{2}$, and the thermometer at 60, they firft exhaufted the prifm, and then applying it to the telefcope, the horizontal hair in the focus covered a mark on the object diftinctly feen through the vacuum, the two glaffes being equally inclined to the vifual ray. Then admitting the air into the prifm, the object was feen to rife above the hair gradually as the air entered, and in the end the hair was obferved to hide a mark $10\frac{1}{4}$ inches below the former mark. This they often repeated, and with the fame fuccefs.

After this they applied the condenfing engine to the prifm; and having forced in another atmofphere, fo that the denfity of the included air was double to to that of the outward, they again placed it before the telefcope, and, letting out the air, the object which before feemed to rife, appeared gradually to defcend, and the hair at length refted on an object higher than before by the fame interval of $10\frac{1}{4}$ inches. This experiment they likewife frequently repeated, without any variation in the event.

They then forced in another atmofphere; and upon difcharging the condenfed air, the object was feen near 21 inches lower than before.

Now the radius in this cafe being 2588 feet, $10\frac{1}{4}$ inches will fubtend an angle of one minute and 8 feconds, and the angle of incidence of the vifual ray being 32 degrees (becaufe the angle of the glafs planes was 64) it follows from the known laws of refraction, that as the fine of 39° is to that of 31°, 59′, 26″, differing from 32° by 34″ the half of 1′, 8″; fo is the fine of any other incidence, to the fine of its angle of refraction; and fo is radius, or 1000000, to 999736; which, therefore, is the proportion between the fine of incidence *in vacuo* and the fine of refraction from thence into common air.

14 Refractive power of the air determined.

It appears, by thefe experiments, that the refractive power of the air is proportionable to its denfity. And fince the denfity of the atmofphere is as its weight directly, and its heat inverfely, the ratio of its denfity, at any given time, may be had by comparing the heights of the barometer and thermometer; and thence he concludes that this will alfo be the ratio of the refraction of the air. But Dr Smith obferves, that, before we can depend upon the accuracy of this conclufion, we ought to examine whether heat and cold alone may not alter the refractive power of air, while its denfity continues the fame. This, he fays, may

may be tried, by heating the condensed or rarified air, shut up in the prism, just before it is fixed to the telescope, and by observing whether the hair in its focus will continue to cover the same mark all the while that the air is cooling.

The French academicians, being informed of the result of the above-mentioned experiment, employed M. Delisle the younger to repeat their former experiment with more care; and he presently found, that their operators had never made any vacuum at all, there being chinks in their instrument, through which the air had insinuated itself. He therefore annexed a gage to his instrument, by which means he was sure of his vacuum; and then the result of the experiment was the same with that in England. The refraction was always in proportion to the density of the air, excepting when the mercury was very low, and consequently the air very rare; in which case the whole quantity being very small, he could not perceive much difference in them. Comparing, however, the refractive power of the atmosphere, observed at Paris, with the result of his experiment, he found, that the best vacuum he could make was far short of that of the etherial regions above the atmosphere.

Dr Hooke first suggested the thought of making allowance for the effect of the refraction of light, in passing from the higher and rarer, to the lower and denser regions of the atmosphere, in the computed height of mountains. To this he ascribes the different opinions of authors concerning the height of several very high hills. He could not account for the appearance of the Pike of Tenerif, and several very high mountains, at so great a distance as that at which they are actually seen, but upon the supposition of the curvature of the visual ray, that is made by its passing obliquely through a medium of such different density, from the top of them to the eye, very far distant in the horizon. All calculations of the height of mountains that are made upon the supposition that the rays of light come from the tops of them, to our eyes, in straight lines, must, he says, be very erroneous.

Dr Hooke gives a very good account of the twinkling of the stars; ascribing it to the irregular and unequal refraction of the rays of light, which is also the reason why the limbs of the sun, moon, and planets appear to wave or dance. And that there is such an unequal distribution of the parts of the atmosphere, he says, is manifest from the different degrees of heat and cold in the air. This, he says, will be evident by looking upon distant objects, over a piece of hot glass, which cannot be supposed to throw out any kind of exhalation from itself, as well as through ascending steams of water.

15 Colours discovered to arise from refraction.

About this time Grimaldi first observed that the coloured image of the sun refracted through a prism is always oblong, and that colours proceed from refraction.—The way in which first he discovered this was by Vitellio's experiment above-mentioned, in which a piece of white paper placed at the bottom of a glass vessel filled with water, and exposed to the light of the sun, appears coloured. However, he observed, that in case the two surfaces of the refracting medium were exactly parallel to each other, no colours were produced. But of the true cause of those colours, viz. the different refrangibility of the rays of light, he had not the least suspicion. This discovery was reserved for Sir Isaac Newton, and which occurred to him in the year 1666. At that time he was busied in grinding optic glasses, and procured a triangular glass prism to satisfy himself concerning the phenomena of colours. While he amused himself with this, the oblong figure of the coloured spectrum first struck him. He was surprised at the great disproportion betwixt its length and breadth; the former being about five times the measure of the latter. He could hardly think that any difference in the thickness of the glass, or in the composition of it, could have such an influence on the light. However, without concluding any thing *à priori*, he proceeded to examine the effects of these circumstances, and particularly tried what would be the consequence of transmitting the light through parts of the glass that were of different thicknesses, or through holes in the window-shutter of different sizes; or by setting the prism on the outside of the shutter, that the light might pass through it, and be refracted before it was terminated by the hole.

16 Different refrangibility of the rays of light discovered by Sir Isaac Newton.

He then suspected that these colours might arise from the light being dilated by some unevenness in the glass, or some other accidental irregularity; and to try this, he took another prism, like the former, and placed it in such a manner, as that the light, passing through them both, might be refracted contrary ways, and so to be returned by the latter into the same course from which he had been diverted by the former. In this manner he thought that the regular effects of the first prism would be destroyed by the second; but that the irregular ones would be augmented by the multiplicity of refractions. The event was, that the light, which by the first prism was diffused into an oblong form, was by the second reduced into a circular one, with as much regularity as if it had not passed through either of them.

At last, after various experiments and conjectures, he hit upon what he calls the *experimentum crucis*, and which completed this great discovery. He took two boards, and placed one of them close behind the prism at the window, so that the light might pass through a small hole made in it for the purpose, and fall on the other board, which he placed at the distance of about 12 feet; having first made a small hole in it also, for some of that incident light to pass through. He then placed another prism behind the second board, so that the light which was transmitted through both the boards might pass through that also, and be again refracted before it arrived at the wall. This being done, he took the first prism in his hand, and turned it about its axis, so much as to make the several parts of the image, cast on the second board, successively to pass through the hole in it, that he might observe to what places on the wall the second prism would refract them; and he saw, by the change of those places, that the light tending to that end of the image towards which the refraction of the first prism was made, did, in the second prism, suffer a refraction considerably greater than the light which tended to the other end. This true cause, therefore, of the length of that image was discovered to be no other, than that light is not similar, or homogeneal; but that it

it conſiſts of rays, ſome of which are more refrangible than others: ſo that, without any difference in their incidence on the ſame medium, ſome of them ſhall be more refracted than others; and therefore, that, according to their particular degrees of refrangibility, they will be tranſmitted through the priſm to different parts of the oppoſite wall.

Since it appears from theſe experiments that different rays of light have different degrees of refrangibility, it neceſſarily follows, that the rules laid down by preceding philoſophers concerning the refractive power of water, glaſs, &c. muſt be limited to the middle kind of rays. Sir Iſaac, however, proves that the ſine of the incidence of every kind of light, conſidered apart, is to its ſine of refraction in a given ratio. This he deduces, both by experiment, and alſo geometrically, from the ſuppoſition that bodies refract the light by acting upon its rays in lines perpendicular to their ſurfaces.

17
Mr Dollond's diſcovery of the method of correcting the faults in refracting teleſcopes.

The moſt important diſcovery with regard to refraction ſince the time of Sir Iſaac Newton is that of Mr Dollond, who found out a method of curing the faults of refracting teleſcopes ariſing from the different refrangibility of the rays, and which had been generally thought impoſſible to be removed.—Notwithſtanding the great diſcovery of Sir Iſaac Newton concerning the different refrangibility of the rays of light, he had no idea but that they were all affected in the ſame proportion by every medium, ſo that the refrangibility of the extreme rays might be determined if that of the mean ones was given. From this it would follow, as Mr Dollond obſerves, that equal and contrary refractions muſt not only deſtroy each other, but that the divergency of the colours from one refraction would likewiſe be corrected by the other, and there could be no poſſibility of producing any ſuch thing as refraction which would not be affected by the different refrangibility of light; or, in other words, that however a ray of light might be refracted backwards and forwards by different mediums, as water, glaſs, &c. provided it was ſo done, that the emergent ray ſhould be parallel to the incident one, it would ever after be white; and conſequently, if it ſhould come out inclined to the incident, it would diverge, and ever after be coloured; and from this it was natural to infer, that all ſpherical object-glaſſes of teleſcopes muſt be equally affected by the different refrangibility of light, in proportion to their apertures, of whatever materials they may be formed.

For this reaſon, Sir Iſaac Newton, and all other philoſophers and opticians, had deſpaired of bringing refracting teleſcopes to any great degree of perfection, without making them of an immoderate and very inconvenient length. They therefore applied themſelves chiefly to the improvement of the reflecting teleſcope; and the buſineſs of refraction was dropped till about the year 1747, when M. Euler, improving upon a hint of Sir Iſaac Newton's, formed a ſcheme of making object-glaſſes of two materials, of different refractive powers; hoping, that by this difference, the refractions would balance one another, and thereby prevent the diſperſion of the rays that is occaſioned by the difference of refrangibility. Theſe object-glaſſes were compoſed of two lenſes of glaſs with water between them. This memoir of M. Euler excited the attention of Mr Dollond. He carefully went over all M. Euler's calculations, ſubſtituting for his hypothetical laws of refraction, thoſe which had been actually aſcertained by the experiments of Newton; and found, that, after this neceſſary ſubſtitution, it followed from M. Euler's own principles, that there could be no union of the foci of all kinds of colours, but in a lens infinitely large.

M. Euler did not pretend to controvert the experiments of Newton: but he ſaid, that they were not contrary to his hypotheſis, but in ſo ſmall a degree as might be neglected; and aſſerted, that, if they were admitted in all their extent, it would be impoſſible to correct the difference of refrangibility occaſioned by the tranſmiſſion of the rays from one medium into another of different denſity; a correction which he thought was very poſſible, ſince he ſuppoſed it to be actually effected in the ſtructure of the eye, which he thought was made to conſiſt of different mediums for that very purpoſe. To this kind of reaſoning Mr Dollond made no reply, but by appealing to the experiments of Newton, and the great circumſpection with which it was known that he conducted all his inquiries.

In this ſtate of the controverſy, the friends of M. Clairaut engaged him to attend to it; and it appeared to him, that, ſince the experiments of Newton cited by Mr Dollond could not be queſtioned, the ſpeculations of M. Euler were more ingenious than uſeful.

The ſame paper of M. Euler was alſo particularly noticed by M. Klingenſtierna of Sweden, who gave a conſiderable degree of attention to the ſubject, and diſcovered, that, from Newton's own principles, the reſult of the 8th experiment of the ſecond book of his Optics could not anſwer his deſcription of it.

He found, he ſays, that when light goes out of air through ſeveral contiguous refracting mediums, as through water and glaſs, and thence goes out again into air, whether the refracting ſurfaces be parallel or inclined to one another, that light, as often as by contrary refractions it is ſo corrected as to emerge in lines parallel to thoſe in which it was incident, continues ever after to be white; but if the emergent rays be inclined to the incident, the whiteneſs of the emerging light will, by degrees, in paſſing on from the place of emergence, become tinged at its edges with colours. This he tried by refracting light with priſms of glaſs, placed within a priſmatic veſſel of water.

By theorems deduced from this experiment he infers, that the refractions of the rays of every ſort, made out of any medium into air, are known by having the refraction of the rays of any one ſort; and alſo that the refraction out of one medium into another is found as often as we have the refractions out of them both into any third medium.

On the contrary, the Swediſh philoſopher obſerves, that, in this experiment, the rays of light, after paſſing through the water and the glaſs, though they come out parallel to the incident rays, will be coloured; but that the ſmaller the glaſs priſm is, the near will the reſult of it approach to Newton's deſcription.

This paper of M. Klingenſtierna, being communicated to Mr Dollond by M. Mallet, made him entertain

tain doubts concerning Newton's report, and determined him to have recourse to experiment.

He therefore cemented together two plates of parallel glafs at their edges, fo as to form a prifmatic veffel, when ftopped at the ends or bafes; and the edge being turned downwards, he placed in it a glafs prifm, with one of its edges upwards, and filled up the vacancy with clear water; fo that the refraction of the prifm was contrived to be contrary to that of the water, in order that a ray of light, tranfmitted through both thefe refracting mediums, might be affected by the difference only between the two refractions. As he found the water to refract more or lefs than the glafs prifm, he diminifhed or increafed the angle between the glafs plates, till he found the two contrary refractions to be equal; which he difcovered by viewing an object thro' this double prifm. For when it appeared neither raifed or depreffed, he was fatisfied that the refractions were equal, and that the emergent rays were parallel to the incident.

Now, according to the prevailing opinion, he obferves, that the object fhould have appeared thro' this double prifm in its natural colour; for if the difference of refrangibility had been in all refpects equal in the two equal refractions, they would have rectified each other. But this experiment fully proved the fallacy of the received opinion, by fhewing the divergency of the light by the glafs prifm, to be almoft double of that by the water; for the image of the object, though not at all refracted, was yet as much infected with prifmatic colours, as if it had been feen thro' a glafs wedge only, whofe refracting angle was near 30 degrees.

This experiment is the very fame with that of Sir Ifaac Newton's above-mentioned, notwithftanding the refult was fo remarkably different: but Mr Dollond affures us, that he ufed all poffible precaution and care in his procefs; and he kept his apparatus by him, that he might evince the truth of what he wrote, whenever he fhould be properly required to do it.

He plainly faw, however, that if the refracting angle of the water veffel could have admitted of a fufficient increafe, the divergency of the coloured rays would have been greatly diminifhed, or entirely rectified; and that there would have been a very great refraction without colour, as he had already produced a great difcolouring without refraction: but the inconveniency of fo large an angle, as that of the prifmatic veffel muft have been, to bring the light to an equal divergency with that of the glafs prifm whofe angle was about 60 degrees, made it neceffary to try fome experiments of the fame kind with fmaller angles.

Accordingly, he got a wedge of plate glafs, the angle of which was only nine degrees; and ufing it in the fame circumftances, he increafed the angle of the water wedge, in which it was placed, till the divergency of the light by the water was equal to that by the glafs; that is, till the image of the object, though confiderably refracted by the excefs of the refraction of the water, appeared neverthelefs quite free from any colours proceeding from the different refrangibility of the light; and, as near as he could then meafure, the refraction by the water was about $\frac{3}{4}$ of that by the glafs. He acknowledges, indeed, that he was not very exact in taking the meafures, becaufe his bufinefs was not at that time to determine the exact proportions, fo much as to fhew that the divergency of the colours, by different fubftances, was by no means in proportion to the refractions, and that there was a poffibility of refraction without any divergency of the light at all.

As thefe experiments clearly proved, that different fubftances made the light to diverge very differently in proportion to their general refractive power, Mr Dollond began to fufpect that fuch variety might poffibly be found in different kinds of glafs, efpecially as experience had already fhewn that fome of the kinds made much better object-glaffes in the ufual way than others; and as no fatisfactory caufe had been affigned for fuch difference, he thought there was great reafon to prefume that it might be owing to the different divergency of the light in the fame refractions.

His next bufinefs, therefore, was to grind wedges of different kinds of glafs, and apply them together; fo that the refractions might be made in contrary directions, in order to difcover, as in the above-mentioned experiments, whether the refraction and the divergency of the colours would vanifh together. But a confiderable time elapfed before he could fet about that work: for tho' he was determined to try it at his leifure, for fatisfying his own curiofity, he did not expect to meet with a difference fufficient to give room for any great improvement of telefcopes, fo that it was not till the latter end of the year 1757 that he undertook it; but his firft trials convinced him that the bufinefs deferved his utmoft attention and application.

He difcovered a difference far beyond his hopes in the refractive qualities of different kinds of glafs, with refpect to the divergency of colours. The yellow or ftraw-coloured foreign fort, commonly called *Venice glafs*, and the *Englifh crown glafs*, proved to be very nearly alike in that refpect; though, in general, the crown glafs feemed to make the light diverge the lefs of the two. The common Englifh plate-glafs made the light diverge more; and the white cryftal, or Englifh flint-glafs, moft of all.

It was now his bufinefs to examine the particular qualities of every kind of glafs that he could come at, not to amufe himfelf with conjectures about the caufe of this difference, but to fix upon two forts in which it fhould be the greateft; and he foon found thefe to be the crown glafs, and the white flint glafs. He therefore ground one wedge of white flint, of about 25 degrees; and another of crown glafs, of about 29 degrees; which refracted very nearly alike, but their power of making the colours diverge was very different. He then ground feveral others of crown glafs to different angles, till he got one which was equal, with refpect to the divergency of the light, to that in the white flint-glafs: for when they were put together, fo as to refract in contrary directions, the refracted light was entirely free from colours. Then meafuring the refraction of each wedge with thefe different angles, he found that of the white glafs to be to that of the crown glafs, nearly as two to three: and this proportion held very nearly in all fmall angles; fo that any two wedges made in this proportion, and applied

plied together, so as to refract in a contrary direction, would refract the light without any dispersion of the rays.

In a letter to M. Klingenstierna, quoted by M. Clairaut, Mr Dollond says, that the sine of incidence in crown glass is to that of its general refraction as 1 to 1.53, and in flint glass as 1 to 1.583.

To apply this knowledge to practice, Mr Dollond went to work upon the object-glasses of telescopes; not doubting but that, upon the same principles on which a refracted colourless ray was produced by prisms, it might be done by lenses also, made of similar materials. And he succeeded, by considering, that, in order to make two spherical glasses that should refract the light in contrary directions, the one must be concave and the other convex; and as the rays are to converge to a real focus, the excess of refraction must evidently be in the convex lens. Also, as the convex glass is to refract the most, it appeared from his experiments, that it must be made of crown glass, and the concave of white flint glass. Farther, as the refractions of spherical glasses are in an inverse ratio of their focal distances, it follows, that the focal distances of the two glasses shall be inversely as the ratios of the refractions of the wedges; for being thus proportioned, every ray of light that passes thro' this combined glass, at whatever distance it may pass from its axis, will constantly be refracted, by the difference between two contrary refractions, in the proportion required; and therefore the different refrangibility of the light will be entirely removed.

Notwithstanding our author had these clear grounds in theory and experiment to go upon, he found that he had many difficulties to struggle with when he came to reduce them into actual practice; but with great patience and address, he at length got into a ready method of making telescopes upon these new principles.

His principal difficulties arose from the following circumstances. In the first place, the focal distances, as well as the particular surfaces, must be very nicely proportioned to the densities or refracting powers of the glasses, which are very apt to vary in the same sort of glass made at different times. Secondly, The centres of the two glasses must be placed truly in the common axis of the telescope, otherwise the desired effect will be in a great measure destroyed. Add to these, that there are four surfaces to be wrought perfectly spherical; and any person, he says, but moderately practised in optical operations, will allow, that there must be the greatest accuracy throughout the whole work. At length, however, after numerous trials, and a resolute perseverance, he was able to construct refracting telescopes, with such apertures and magnifying powers, under limited lengths, as, in the opinion of the best judges, far exceeded any thing that had been produced before, representing objects with great distinctness, and in their true colours.

It was objected to Mr Dollond's discovery, that the small dispersion of the rays in crown glass is only apparent, owing to the opacity of that kind of glass which does not transmit the fainter coloured rays in a sufficient quantity; but this objection is particularly considered, and answered by M. Beguelin.

As Mr Dollond did not explain the methods which he took in the choice of different spheres proper to destroy the effect of the different refrangibility of the rays of light, and gave no hint that he himself had any rule to direct himself in it; and as the calculation of the dispersion of the rays, in so complicated an affair, is very delicate; M. Clairaut, who had given a good deal of attention to this subject, from the beginning of the controversy, endeavoured to make out a complete theory of it.

Without some assistance of this kind, it is impossible, says this author, to construct telescopes of equal goodness with those of Mr Dollond, except by a servile imitation of his; which, however, on many accounts, would be very unlikely to answer. Besides, Mr Dollond only gave his proportions in general, and pretty near the truth; whereas the greatest possible precision is necessary. Also the best of Mr Dollond's telescopes were far short of the Newtonian ones (A); whereas it might be expected that they should exceed them, if the foci of all the coloured rays could be as perfectly united after refraction thro' glass, as after reflexion from a mirror; since there is more light lost in the latter case than in the former.

With a view, therefore, to assist the artist, he endeavoured to ascertain the refractive power of different kinds of glass, and also their property of separating the rays of light, by the following exact methods. He made use of two prisms placed close to one another, as Mr Dollond had done: but, instead of looking thro' them, he placed them in a darkened room; and when the image of the sun, transmitted thro' them, was perfectly white, he concluded that the different refrangibility of the rays was corrected.

In order to ascertain with more ease the true angles that prisms ought to have to destroy the effect of the difference of refrangibility, he constructed one which had one of its surfaces cylindrical, with several degrees of amplitude. By this means, without changing his prisms, he had the choice of an infinity of angles; among which, by examining the point of the curve surface, which, receiving the solar ray, gave a white image, he could easily find the true one.

He also ascertained the proportion in which different kinds of glass separated the rays of light, by measuring, with proper precautions, the oblong image of the sun, made by transmitting a beam of light thro' them. In making these experiments, he hit upon an easy method of convincing any person of the greater refractive power of English flint-glass above the common French glass, both with respect to the mean refraction, and the different refrangibility of the colours; for having taken two prisms, of these two kinds of glass, but equal in all other respects, and placed them so that they received, at the same time, two rays of the sun, with the same degree of incidence, he saw, that, of the two images, that which was produced by the English flint-glass was a little higher upon the wall than the other, and longer by more than one half.

M. Clairaut was assisted in these experiments by M. De Tournieres, and the results agreed with Mr Dollond's

(A) This assertion of M. Clairaut might be true at the time that it was made, but it is by no means so at present.

lond's in general; but whereas Mr Dollond had made the difperfion of the rays in glafs and in water to be as five to four (acknowledging, however, that he did not pretend to do it with exactnefs) thefe gentlemen, who took more pains, and ufed more precautions, found it to be as three to two. For the theorems and problems deduced by M. Clairaut from thefe new principles of optics, with a view to the perfection of telefcopes, we muft refer the reader to *Mem. Acad. Par.* 1756, 1757.

The labours of M. Clairaut were fucceeded by thofe of M. D'Alembert, which feem to have given the makers of thefe achromatic telefcopes all the aid that calculations can afford them. This excellent mathematician has likewife propofed a variety of new conftructions of thefe telefcopes, the advantages and difadvantages of which he diftinctly notes; at the fame time that he points out feveral methods of correcting the errors to which they are liable: as by placing the object-glaffes, in fome cafes, at a fmall diftance from one another, and fometimes by ufing eye-glaffes of different refractive powers; which is an expedient that feems not to have occurred to any perfon before him. He even fhews, that telefcopes may be made to advantage, confifting of only one object-glafs, and an eye-glafs of a different refractive power. Some of his conftructions have two or more eye-glaffes of different kinds of glafs. This fubject he confidered at large in one of the volumes of his *Opufcules Mathematiques*. We have alfo three memoirs of M. D'Alembert upon this fubject, among thofe of the French Academy; one in the year 1764, another in 1765, and a third in 1767.

At the conclufion of his fecond memoir he fays, that he does not doubt, but, by the different methods he propofes, achromatic telefcopes may be made to far greater degrees of perfection than any that have been feen hitherto, and even fuch as is hardly credible: And tho' the crown glafs, by its greenifh colour, may abforb fome part of the red or violet rays, which, however, is not found to be the cafe in fact; that objection cannot be made to the common French glafs, which is white, and which on this account he thinks muft be preferable to the Englifh crown glafs.

Nothwithftanding Meffrs Clairaut and D'Alembert feemed to have exhaufted the bufinefs of calculation on the fubject of Mr Dollond's telefcopes, no ufe could be made of their labours by foreign artifts. For ftill the telefcopes made in England, according to no exact rule, as foreigners fuppofed, were greatly fuperior to any that could be made elfe where, though under the immediate direction of thofe able calculators. For this M. Beguelin affigned feveral reafons. Among others, he thought that their geometrical theorems were too general, and their calculations too complicated, for the ufe of workmen. He alfo thought, that in confequence of neglecting fmall quantities, which thefe calculators profeffedly did, in order to make their algebraical expreffions more commodious, their conclufions were not fufficiently exact. But what he thought to be of the moft confequence, was the want of an exact method of meafuring the refractive and difperfing powers of the different kinds of glafs; and for want of this, the greateft precifion in calculation was altogether ufelefs.

Thefe confiderations induced this gentleman to take another view of this fubject; but ftill he could not reconcile the actual effect of Mr Dolland's telefcopes with his own conclufions: fo that he imagined, either that he had not the true refraction and difperfion of the two kinds of glafs given him; or elfe, that the aberration which ftill remained after his calculations, muft have been deftroyed by fome irregularity in the furfaces of the lenfes. He finds feveral errors in the calculations both of M. D'Alembert and Clairaut, and concludes with expreffing his defign to purfue this fubject much farther.

M. Euler, who firft gave occafion to this inquiry, which terminated fo happily for the advancement of fcience, being perfuaded both by his reafoning and calculations, that Mr Dollond had difcovered no new principle in optics, and yet not being able to controvert Mr Short's teftimony in favour of the goodnefs of his telefcopes, concluded that this extraordinary effect was owing, in part, to the crown glafs not tranfmitting all the red light, which would otherwife have come to a different focus, and have diftorted the image; but principally to his happening to hit on a juft curvature of his glafs, which he did not doubt would have produced the fame effect if his lenfes had all been made of the fame kind of glafs. In another place he imagines that the goodnefs of Mr Dollond's telefcope might be owing to the eye-glafs. If my theory, fays he, be true, this difagreeable confequence follows, that Mr Dollond's object-glaffes cannot be exempt from the difperfion of colours: yet a regard to fo refpectable a teftimony embarraffes me extremely, it being as difficult to queftion fuch exprefs authority, as to abandon a theory which appears me perfectly well founded, and to embrace an opinion, which is as contrary to all the eftablifhed laws of nature, as it is ftrange and feemingly abfurd. He even appeals to experiments made in a darkened room; in which, he fays, he is confident that Mr Dollond's object-glaffes would appear to have the fame defects that others are fubject to.

No doubting, however, but that Mr Dollond, either by chance, or otherwife, had made fome confiderable improvement in the conftruction of telefcopes, by the combination of glaffes; he abandoned his former project, in which he had recourfe to different mediums, and confined his attention to the correction of the errors which arife from the curvature of lenfes. But while he was proceeding, as he imagined, upon the true principles of optics, of which, however, he made but little ufe, he could not help expreffing his furprife that Mr Dollond fhould have been led to fo important a difcovery by reafoning in a manner quite contrary to the nature of things. At length, however, Mr Euler was convinced of the reality and importance of Mr Dollond's difcoveries; and very frankly acknowledges, that he fhould, perhaps, never have been brought to affent to it, had not his friend M. Clairaut affured him that the experiments of the Englifh optician might be depended upon. However, the experiments of M. Zeiher of Peterfburgh gave him the moft complete fatisfaction with refpect to this new law of refraction.

This gentleman demonftrated, that it is the lead in the compofition of glafs that gives it this remarkable property,

property, that while the refraction of the mean rays is nearly the ſame, that of the extremes differs conſiderably. And, by increaſing the quantity of lead in the mixture, he produced a kind of glaſs, which occaſioned a much greater ſeparation of the extreme rays than the flint-glaſs which Mr Dollond had made uſe of. By this evidence M. Euler owns that he was compelled to renounce the principle which, before this time, had been conſidered as inconteſtible, *viz.* that the diſperſion of the extreme rays depends upon the refraction of the mean; and that the former varies with the quality of the glaſs, while the latter is not affected by it.

From theſe new principles M. Euler deduces theorems concerning the combination of the lenſes, and, in a manner ſimilar to M. Clairaut and D'Alembert, points out methods of conſtructing achromatic teleſcopes.

18 Different compoſitions of glaſs for the purpoſe of correcting the faults of refracting teleſcopes.

While he was employed upon this ſubject, he informs us, that he received a letter from M. Zeiher, dated Peterſburgh 30th of January 1764, in which he gives him a particular account of the ſucceſs of his experiments on the compoſition of glaſs; and that, having mixed minium and ſand in different proportions, the reſult of the mean refraction and the diſperſion of the rays varied according to the following table.

Proportion of minium to flint.	Mean refraction from air into glaſs.	Diſperſion of the rays in compariſon of crown-glaſs.
I. — 3 : 1	2028 : 1000	4800 : 1000
II. — 2 : 1	1830 : 1000	3550 : 1080
III. — 1 : 1	1787 : 1000	3259 : 1000
IV. — $\frac{3}{4}$: 1	1732 : 1000	2207 : 1000
V. — $\frac{1}{2}$: 1	1724 : 1000	1800 : 1000
VI. — $\frac{1}{4}$: 1	1664 : 1000	1354 : 1000

By this table it is evident, that a greater quantity of lead not only occaſions a greater diſperſion of the rays, but alſo conſiderably increaſes the mean refraction. The firſt of theſe kinds of glaſs, which contains three times as much minium as flint, will appear very extraordinary; ſince, hitherto, no tranſparent ſubſtance has been known, whoſe refractive power exceded the ratio of two to one, and that the diſperſion occaſioned by this glaſs is almoſt five times as great at that of crown glaſs, which could not be believed by thoſe who entertained any doubt concerning the ſame property in flint glaſs, the effect of which is three times as great as crown glaſs. One may obſerve, however, in theſe kinds of glaſs, ſomething of a proportion between the mean refraction and the diſperſion of rays, which may enable us to reconcile theſe ſurpriſing effects with other principles already known,

Here, however, M. Euler announces to us another diſcovery of the ſame M. Zeiher, no leſs ſurpriſing than the former, and which diſconcerted all his ſchemes for reconciling the above-mentioned phenomena. As the ſix kinds of glaſs mentioned in the above table were compoſed of nothing but minium and flint, M. Zeiher happened to think of mixing alkaline ſalts with them, in order to give the glaſs a conſiſtence more proper for dioptric uſes; when he was much ſurpriſed to find this mixture greatly diminiſhed the mean refraction, almoſt without making any change in the diſperſion. After many trials, he at length obtained a kind of glaſs greatly ſuperior to the flint-glaſs of Mr Dollond, with reſpect to the conſtruction of teleſcopes; ſince it occaſioned three times as great a diſperſion of the rays as the common glaſs, at the ſame time that the mean refraction was only as 1.61 to 1.

M. Euler alſo gives particular inſtructions how to find both the mean and extreme refractive power of different kinds of glaſs; and particularly adviſes to make uſe of priſms with very large refracting angles, not leſs than 70°.

Notwithſtanding it evidently appeared, we may ſay, to almoſt all philoſophers, that Mr Dollond had made a real diſcovery of ſomething not comprehended in the optical principles of Sir Iſaac Newton, it did not appear ſo to Mr Murdoch. Upon this occaſion, he interpoſed in the defence, as he imagined, of Sir Iſaac Newton; maintaining, that Mr Dollond's poſitions, which, he ſays, he knows not by what miſhap have been deemed paradoxes in Sir Iſaac's theory of light, are really the neceſſary conſequences of it. He alſo endeavours to ſhew that Sir Iſaac might not be miſtaken in his account of the experiment above-mentioned. But, admitting all that he advances in this part of his defence, Newton muſt have made uſe of a priſm with a much ſmaller refracting angle than, from his own account of his experiments, we have any reaſon to believe that he ever did make uſe of.

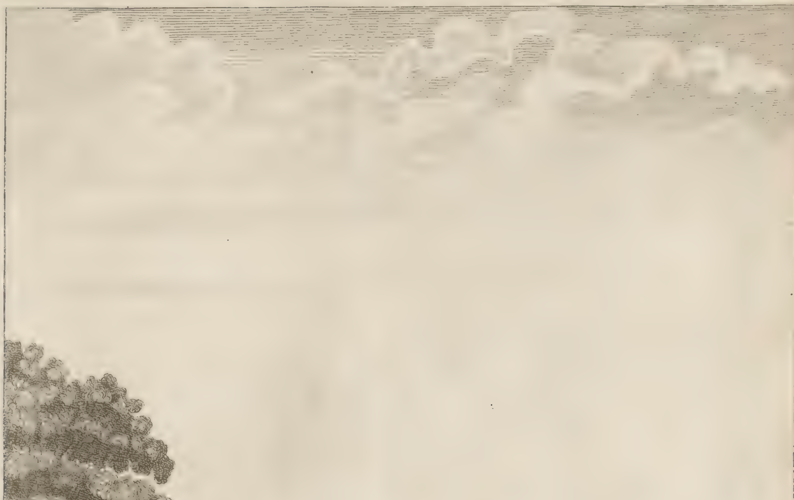
The fact probably was, that Sir Iſaac deceived himſelf in this caſe, by attending to what he imagined to be the clear conſequence of his other experiments; and though the light he ſaw was certainly tinged with colours, and he muſt have ſeen it to be ſo, yet he might imagine that this circumſtance aroſe from ſome imperfection in his priſms, or in the diſpoſition of them, which he did not think it worth his while to examine. It is alſo obſervable, that Sir Iſaac is not ſo particular in his deſcription of his priſms, and other parts of his apparatus, in his account of this experiment, as he generally is in other caſes; and therefore, probably, wrote his account of it from his memory only. In reality, it is no reflection upon Sir Iſaac Newton, who did ſo much, to ſay that he was miſtaken in this particular caſe, and that he did not make the diſcovery that Mr Dollond did; though it be great praiſe to Mr Dollond, and all thoſe perſons who contributed to this diſcovery, that they ventured to call in queſtion the authority of ſo great a man.

19 Of the refraction of the atmoſphere.

We ſhall conclude the hiſtory of the diſcoveries concerning refraction, with ſome account of the refractions of the atmoſphere.—Tables of this have been calculated by Mr Lambert with a view to correct the inaccuracies of geometrical obſervations of the altitudes of mountains. The obſervations of Mr Lambert, however, go upon the ſuppoſition that the refractive power of the atmoſphere is invariable: But this is by no means the caſe; and therefore his rules muſt be conſidered as true for the mean ſtate of the air only.

A moſt remarkable variety in the refractive power of the atmoſphere was obſerved by Dr Nettleton, near Halifax in Yorkſhire, which demonſtrates how little we can depend upon the calculated heights of mountains, when the obſervations are made with an inſtrument, and the refractive power of the air is to be allowed

Bramin's OBSERVATORY. Plate CCV.



A Bell Sculp.

lowed for. Being deſirous to learn, by obſervation, how far the mercury would deſcend in the barometer at any given elevation, (for which there is the beſt opportunity in that hilly country), he propoſed to take the height of ſome of their higheſt hills; but when he attempted it, he found his obſervation ſo much diſturbed by refraction, that he could come to no certainty. Having meaſured one hill of a conſiderable height, in a clear day, and obſerved the mercury at the bottom and at the top, he found, according to that eſtimation, that about 90 feet, or more, were required to make the mercury fall $\frac{1}{10}$ of an inch; but afterwards, repeating the experiment on a cloudy day, when the air was rather groſs and hazy, he found the ſmall angles ſo much increaſed by refraction as to make the hill much higher than before. He afterwards frequently made obſervations at his own houſe, by pointing a quadrant to the tops of ſome neighbouring hills, and obſerved that they would appear higher in the morning before ſun-riſe, and alſo late in the evening, than at noon in a clear day, by ſeveral minutes. In one caſe the elevations of the ſame hill differed more than 30 minutes. From this he infers, that obſervations made on very high hills, eſpecially when viewed at a diſtance, and under ſmall angles, as they generally are, are probably uncertain, and not much to be depended upon.

M. Euler conſidered with great accuracy the refractive power of the atmoſphere, as affected by different degrees of heat and elaſticity, in which he ſhews, that its refractive power, to a conſiderable diſtance from the zenith, is ſufficiently near the proportion of the tangent of that diſtance, and that the law of refraction follows the direct ratio of the height of the barometer, and the inverſe ratio of the difference marked by the thermometer; but when ſtars are in the horizon, the changes are in a ratio ſomewhat greater than this, more eſpecially on account of the variation in the heat.

20 Mr Michell's opinion concerning the twinkling of the ſtars.

The cauſe of the twinkling of the ſtars is now generally acknowledged to be the unequal refraction of light, in conſequence of inequalities and undulations in the atmoſphere.

Mr Michell ſuppoſes that the arrival of fewer or more rays at one time, eſpecially from the ſmaller or the more remote fixed ſtars, may make ſuch an unequal impreſſion upon the eye, as may, at leaſt, have ſome ſhare in producing this effect; ſince it may be ſuppoſed, that even a ſingle particle of light is ſufficient to make a ſenſible impreſſion upon the organs of ſight; ſo that very few particles arriving at the eye in a ſecond of time, perhaps no more than three or four, may be ſufficient to make an object conſtantly viſible. For though the impreſſion may be conſidered as momentary, yet the perception occaſioned by it is of ſome duration. Hence, he ſays, it is not improbable that the number of the particles of light which enter the eye in a ſecond of time, even from Sirius himſelf, (the light of which does not exceed that of the ſmalleſt viſible fixed ſtar, in a greater proportion than that of about 1000 to 1), may not exceed 3000 or 4000, and from ſtars of the ſecond magnitude they may, therefore, probably not exceed 100. Now the apparent increaſe and diminution of the light which we obſerve in the twinkling of the ſtars, ſeems to be repeated at not very unequal intervals, perhaps about four or five times in a ſecond. He therefore thought it reaſonable to ſuppoſe, that the inequalities which will naturally ariſe from the chance of the rays coming ſometimes a little denſer, and ſometimes a little rarer, in ſo ſmall a number of them, as muſt fall upon the eye in the fourth or fifth part of a ſecond, may be ſufficient to account for this appearance. An addition of two or three particles of light, or perhaps a ſingle one, upon 20, eſpecially if there ſhould be an equal deficiency out of the next 20, would, he ſuppoſed, be very ſenſible, as he thought was probable from the very great difference in the appearance of ſtars, the light of which does not differ ſo much as is commonly imagined. The light of the middlemoſt ſtar in the tail of the great bear does not, he thinks, exceed the light of the very ſmall ſtar that is next to it in a greater proportion than that of about 16 or 20 to 1; and M. Bouger found, that a difference in the light of objects of one part in 66 was ſufficiently diſtinguiſhable.

It will perhaps, he ſays, be objected, that the rays coming from Sirius are too numerous to admit of a ſufficient inequality ariſing from the common effect of chance, ſo frequently as would be neceſſary to produce this effect, whatever might happen with reſpect to the ſmaller ſtars; but he obſerves, that, till we know what inequality is neceſſary to produce this effect, we can only gueſs at it one way or the other.

Since theſe obſervations were publiſhed, Mr Michell has entertained ſome ſuſpicion that the unequal denſity of light does not contribute to this effect in ſo great a degree as he had imagined, eſpecially in conſequence of obſerving that even Venus does ſometimes twinkle. This he once obſerved her to do remarkably when ſhe was about 6 degrees high, though Jupiter, which was then about 16 degrees high, and was ſenſibly leſs luminous, did not twinkle at all. If, notwithſtanding the great number of rays which, no doubt, come to the eye from ſuch a ſurface as this planet preſents, its appearance be liable to be affected in this manner, it muſt be owing to ſuch undulations in the atmoſphere, as will probably render the effect of every other cauſe altogether inſenſible. The conjecture, however, has ſo much probability in it, that it well deſerved to be recited.

21 Mr Muſchenbroek's opinion.

M. Muſchenbroek ſuſpects, that the twinkling of the ſtars ariſes from ſome affection of the eye, as well as the ſtate of the atmoſphere. For he ſays, that in Holland, when the weather is froſty, and the ſky very clear, the ſtars twinkle moſt manifeſtly to the naked eye, though not in teleſcopes; and ſince he does not ſuppoſe that there is any great exhalation, or dancing of the vapour at that time, he queſtions whether the vivacity of the light affecting the eye may not be concerned in the phenomenon.

But this philoſopher might very eaſily have ſatisfied himſelf with reſpect to this hypotheſis, by looking at the ſtars near the zenith, when the light traverſes but a ſmall part of the atmoſphere, and therefore might be expected to affect the eye the moſt ſenſibly. For he would not have perceived them to twinkle near ſo much, as they do nearer the horizon, when much more of their light is intercepted by the atmoſphere.

Some aſtronomers have lately endeavoured to explain the twinkling of the fixed ſtars by the extreme minuteneſs of their apparent diameter; ſo that

 they

they ſuppoſe the ſight of them is intercepted by every mote that floats in the air. But Mr Michell obſerves, that no object can hide a ſtar from us that is not large enough to exceed the apparent diameter of the ſtar, by the diameter of the pupil of the eye; ſo that if a ſtar was a mathematical point, the interpoſing object muſt ſtill be equal in ſize to the pupil of the eye: nay, it muſt be large enough to hide the ſtar from both eyes at the ſame time.

Beſides a variation in the quantity of light, a momentary change of colour has likewiſe been obſerved in ſome of the fixed ſtars. Mr Melville ſays, that when one looks ſtedfaſtly at Sirius, or any bright ſtar not much elevated above the horizon, its colour ſeems not to be conſtantly white, but appears tinctured, at every twinkling, with red and blue. This obſervation Mr Melville puts among his queries, with reſpect to which he could not entirely ſatisfy himſelf; and he obſerves, that the ſeparation of the colours by the refractive power of the atmoſphere is, probably, too ſmall to be perceived. But the ſuppoſition of Mr Michell above-mentioned will pretty well account for this circumſtance, though it may be thought inadequate to the former caſe. For the red and blue rays being much fewer than thoſe of the intermediate colours, and therefore much more liable to inequalities, from the common effect of chance, a ſmall exceſs or defect in either of them will make a very ſenſible difference in the colour of the ſtars.

§ 3. *Diſcoveries concerning the Reflection of Light.*

22 Account of the diſcoveries of the ancients.

However much the ancients might have been miſtaken with regard to the nature of light, we find that they were acquainted with two very important obſervations concerning it; viz. that light is propagated in right lines, and that the angle of incidence is equal to the angle of reflection. Who it was that firſt made theſe important obſervations is not known. But indeed, important as they are, and the foundation of a great part of even the preſent ſyſtem of optics, it is poſſible that, if he were known, he might not be allowed to have any ſhare of merit, at leaſt for the *former* of them; the fact is ſo very obvious, and ſo eaſily aſcertained. As to the latter, that *the angle of incidence is equal to the angle of reflection* it was probably firſt diſcovered by obſerving a ray of the ſun reflected from the ſurface of water, or ſome other poliſhed body; or from obſerving the images of objects reflected by ſuch ſurfaces. If philoſophers attended to this phenomenon at all, they could not but take notice, that, if the ray fell nearly perpendicular upon ſuch a ſurface, it was reflected near the perpendicular; and if it fell obliquely, it was reflected obliquely: and if they thought of applying any kind of meaſures to theſe angles, however coarſe and imperfect, they could not but ſee that there was ſufficient reaſon to aſſert their equality. At the ſame time they could not but know that the incident and reflected rays were both in the ſame plane.

Ariſtotle was ſenſible that it is the reflection of light from the atmoſphere which prevents total darkneſs after the ſun ſets, and in places where he doth not ſhine in the day-time. He was alſo of opinion, that rainbows, halos, and mock ſuns, were all occaſioned by the reflection of the ſunbeams in different circumſtances, by which an imperfect image of his body was produced, the colour only being exhibited, and not his proper figure. The image, he ſays, is not ſingle, as in a mirror; for each drop of rain is too ſmall to reflect a viſible image, but the conjunction of all the images is viſible.

23 Euclid's treatiſe of optics.

Without inquiring any farther into the nature of light or viſion, the ancient geometricians contented themſelves with deducing a ſyſtem of optics from the two obſervations mentioned above, viz. the rectilinear progreſs of light, and the equality of the angles of incidence and reflection. The treatiſe of optics which has been aſcribed to Euclid is employed about determining the aparent ſize and figure of objects, from the angle under which they appear, or which the extremities of them ſubtend at the eye, and apparent place of the image of an object reflected from a poliſhed mirror; which he fixes at the place where the reflected ray meets a perpendicular to the mirror drawn through the object. But this work is ſo imperfect, and ſo inaccurately drawn up, that it is not generally thought to be the production of that great geometrician.

24 Of the burning-glaſſes of the ancients.

It appears from a circumſtance in the hiſtory of Socrates, that the effects of burning-glaſſes had alſo been obſerved by the ancients; and it is probable that the Romans had a method of lighting their ſacred fire by means of a concave ſpeculum. It ſeems indeed to have been known pretty early, that there is an increaſe of heat in the place where the rays of light meet, when they are reflected from a concave mirror. The burning power of concave mirrors is taken notice of by Euclid in the ſecond book of the treatiſe abovementioned. If we give but a ſmall degree of credit to what ſome ancient hiſtorians are ſaid to have written concerning the exploits of Archimedes, we ſhall be induced to think that he made great uſe of this principle, in conſtructing ſome very powerful burning-mirrors; but nothing being ſaid of other perſons making uſe of his inventions, the whole account is very doubtful. It is allowed, however, that this eminent geometrician did write a treatiſe on the ſubject of burning-mirrors, though it be not now extant.

B. Porta ſuppoſes that the burning-mirrors of the ancients were of metal, in the form of a ſection of a parabola. It follows from the properties of this curve, that all the rays which fall upon it, parallel to its axis, will meet in the ſame point at the focus. Conſequently, if the vertex of the parabola be cut off, as in fig. 1. it will make a convenient burning-mirror. Plate CCVI
In ſome drawings of this inſtrument fruſtum is ſo ſmall, as to look like a ring. With an inſtrument of this kind, it is thought, that the Romans lighted their ſacred fire. Some have alſo thought that this was the form of the mirror with which Archimedes burnt the Roman fleet; uſing either a lens, to throw the rays parallel, when they had been brought to a focus; or applying a ſmaller parabolic mirror for this purpoſe, as is repreſented fig. 2. But Dechales ſhows, that it is impoſſible to convey any rays in a direction parallel to one another, except thoſe that come from the ſame point in the ſun's diſk.

25 Of ſeeing images in the air.

All this time, however, the nature of reflection was very far from being underſtood. Even lord Bacon, who

who made much greater advances in natural philosophy than his predecessors, and who pointed out the true method of improving it, was so far deceived with regard to the nature of reflection and refraction, that he supposed it possible to see the image reflected from a looking-glass, without seeing the glass itself; and to this purpose he quotes a story of friar Bacon, who is reported to have apparently walked in the air between two steeples, and which was thought to have been effected by reflection from glasses while he walked upon the ground.

The whole business of seeing images in the air may be traced up to Vitellio; and what he said upon the subject seems to have passed from writer to writer, with considerable additions, to the time of lord Bacon. What Vitellio endeavours to shew is, that it is possible, by means of a cylindrical convex speculum, to see the images of objects in the air, out of the speculum, when the objects themselves cannot be seen. But, if his description of the apparatus requisite for this experiment be attended to, it will be seen that the eye was to be directed towards the speculum, which was placed within a room, while both the object and the spectator were without it. But though he recommends this observation to the diligent study of his readers, he has not described it in such a manner as is very intelligible; and, indeed, it is certain, that no such effect can be produced by a convex mirror. If he himself did make any trial with the apparatus that he describes for this purpose, he must have been under some deception with respect to it.

B. Porta says, that this effect may be produced by a plane mirror only; and that an ingenious person may succeed in it: but his more particular description of a method to produce this extraordinary appearance is by a plane mirror and a concave one combined.

Kircher also speaks of the possibility of exhibiting these pendulous images, and supposes that they are reflected from the dense air; and the most perfect and pleasing deception depending upon the images in the air is one of which this writer gives a particular account in his *Ars Magna Lucis et Umbræ*, p. 783. In this case the image is placed at the bottom of a hollow polished cylinder, by which means it appears like a real solid substance, suspended within the mouth of the vessel. In this manner, he says, he once exhibited a representation of the ascension of Christ; when the images were so perfect, that the spectators could not be persuaded, but by attempting to handle them, that they were not real substances.

Among other amusing things that were either invented or improved by Kircher, was the method of throwing the appearance of letters, and other forms of things, into a darkened room from without, by means of a lens and a plane mirror. The figures or letters were written upon the face of the mirror, and inverted; and the focus of the lens was contrived to fall upon the screen or wall that received their images. In this manner, he says, that with the light of the sun he could throw a plain and distinct image 500 feet.

26 Discoveries of Kepler and Gregory.

It was Kepler who first discovered the true reason of the apparent places of objects seen by reflecting mirrors, as it depends upon the angle which the rays of light, issuing from the extreme part of an object, make with one another after such reflections. In plane mirrors these rays are reflected with the same degree of inclination to one another that they had before their incidence; but he shews that this inclination is changed in convex and concave mirrors.

27 Of Mr Boyle.

Mr Boyle made some curious observations concerning the reflecting powers of differently coloured substances. Many learned men, he says, imagined that snow affects the eyes, not by a *borrowed*, but by a *native* light; but having placed a quantity of snow in a room from which all foreign light was excluded, neither he nor any body else was able to perceive it. To try whether white bodies reflect more light than others, he held a sheet of white paper in a sun-beam admitted into a darkened room; and observed that it reflected much more light than a paper of any other colour, a considerable part of the room being enlightened by it. Farther, to shew that white bodies reflect the rays outwards, he adds, that common burning-glasses will not of a long time burn or discolour white paper. When he was a boy, he says, and took great pleasure in making experiments with these glasses, he was much surprised at this remarkable circumstance; and it set him very early upon guessing at the nature of whiteness, especially as he observed that the image of the sun was not so well defined upon white paper as upon black; and as, when he put ink upon the paper, the moisture would be quickly dried up, and the paper, which he could not burn before, would presently take fire. He also found, that, by exposing his hand to the sun, with a thin black glove upon it, it would be suddenly and more considerably heated, than if he held his naked hand to the rays, or put on a glove of thin white leather.

To prove that black is the reverse of white, with respect to its property of reflecting the rays of the sun, he procured a large piece of black marble; and having got it ground into the form of a large spherical concave speculum, he found that the image of the sun reflected from it was far from offending or dazzling his eyes, as it would have done from another speculum; and tho' this was large, he could not in a long time set a piece of wood on fire with it; tho' a far less speculum, of the same form, and of a more reflecting substance, would presently have made it flame.

To satisfy himself still farther with respect to this subject, he took a broad and large tile; and having made one half of its surface white and the other black, he exposed it to the summer sun. And having let it lie there some time, he found, that while the whited part remained cool, the part that was black was grown very hot. For his farther satisfaction, he sometimes left part of the tile of its native red; and, after exposing the whole to the sun, observed that this part grew hotter than the white, but was not so hot as the black part. He also observes, that rooms hung with black are not only darker than they would otherwise be, but warmer too; and he knew several persons, who found great inconvenience from rooms hung with black. As another proof of his hypothesis, he informs, that a virtuoso, of unsuspected credit, acquainting him, that, in a hot climate, he had seen eggs well roasted in a short time, by first blacking the shells, and then exposing them to the sun.

28 Of the infusion of lignum nephriticum.

We have already taken notice of the remarkable property of lignum nephriticum first observed by Kircher.

cher. However, all his obfervations with regard to it fell very fhort of Mr Boyle. He defcribes this lignum nephriticum to be a whitifh kind of wood, that was brought from Mexico, which the natives call *coatl* or *tlapazatli*, and which had been thought to tinge water of a green colour only; but he fays that he found it to communicate all kinds of colours. If, fays he, an infufion of this wood be put into a glafs globe, and expofed to a ftrong light, it will be as colourlefs as pure water; but if it be carried into a place a little fhaded, it will be a moft beautiful green. In a place ftill more fhaded, it will incline to red; and in a very fhady place, or in an opaque veffel, it will be green again.

A cup of this remarkable wood was fent to Kircher by the procurator of his fociety at Mexico, and was prefented by him to the emperor as a great curiofity. It is called *lignum nephriticum*, becaufe the infufion of it was imagined to be of fervice in difeafes of the kidneys and bladder, and the natives of the country where it grows do make ufe of it for that purpofe.

Mr Boyle corrected feveral of the hafty obfervations of Kircher concerning the colours that appear in the infufion of lignum nephriticum, and he diverfified the experiments with it in a very pleafing manner. He firft diftinctly noted the two very different colours which this remarkable tincture exhibits, by tranfmitted and reflected light. If, fays he, it be held directly between the light and the eye, it will appear tinged (excepting the very top of it, where a fky-coloured circle fometimes appears) almoft of a golden colour, except the infufion be too ftrong; in which cafe it will be dark or reddifh, and requires to be diluted with water. But if it be held from the light, fo that the eye be between the light and the phial, it will appear of a deep lovely blue colour; as will alfo the drops, if any lie on the outfide of the glafs.

When a little of this tincture was poured upon a fheet of white paper, and placed in a window where the fun could fhine upon it, he obferved, that if he turned his back upon the fun, the fhadow of his pen, or any fuch flender fubftance, projected upon the liquor, would not be all dark, like other fhadows; but that part of it would be curioufly coloured, the edge of it next the body being almoft of a lively golden colour, and the more remote part blue. Thefe, and other experiments of a fimilar nature, many of his friends, he fays, beheld with wonder; and he remembered an excellent oculift, who accidentally meeting with a phial full of this liquor, and being unacquainted with this remarkable property of it, imagined, after he had viewed it a long time, that fome new and ftrange diftemper had feized his eyes: and Mr Boyle himfelf acknowledges, that the oddnefs of the phenomenon made him very defirous to find out the caufe of it; and his inquiries were not altogether unfuccefsful.

Obferving that this tincture, if it were too deep, was not tinged in fo beautiful a manner, and that the impregnating virtue of the wood did, by being frequently infufed in frefh water, gradually decay, he conjectured that the tincture contained much of the effential falt of the wood; and to try whether the fubtle parts, on which the colour depended, were volatile enough to be diftilled, without diffolving their texture, he applied fome of it to the gentle heat of a lamp-furnace; but he found all that came over was as limpid and colourlefs as rock water, while that which remained behind was of fo deep a blue, that it was only in a very ftrong light that it appeared of any colour.

Sufpecting that the tinging particles abounded with falts, whofe texture, and the colour thence arifing, would probably be altered by acids, he poured into a fmall quantity of it a very little fpirit of vinegar, and found that the blue colour immediately vanifhed, while the golden one remained, on which ever fide it was viewed with refpect to the light.

Upon this he imagined, that as the acid falts of the vinegar had been able to deprive the liquor of its blue colour, a fulphureous falt, which is of a contrary nature, would deftroy their effects; and having placed himfelf betwixt the window and the phial, and let fall into the fame liquor a few drops of oil of tartar *per deliquium*, he found that it was immediately reftored to its former blue colour, and exhibited all the fame phenomena which it had done at the firft.

Having fometimes brought a round long-necked phial, filled with this tincture, into a darkened room, into which a beam of the fun was admitted by a fmall aperture; and holding the phial fometimes near the fun-beams, and fometimes partly in them and partly out of them, changing alfo the pofition of the glafs, and viewing it from feveral parts of the room, it exhibited a much greater variety of colours than it did in an enlightened room. Befides the ufual colours, it was red in fome places, and green in others, and within were intermediate colours produced by the different degrees and odd mixtures of light and fhade.

It was not only in this tincture of lignum nephriticum that Mr Boyle obferved the difference between reflected and tranfmitted light. He obferved it even in gold, tho' no perfon explained the caufe of thefe effects before Sir Ifaac Newton. He took a piece of leaf-gold, and holding it betwixt his eye and the light, obferved that it did not appear of a golden colour, but of a greenifh blue. He alfo obferved the fame change of colour by candle-light; but the experiment did not fucceed with a leaf of filver.

The conftitution of the atmofphere and of the fea, we fhall find, by obfervations made in later periods, to be fimilar to that of this infufion; for the blue rays, and others of a faint colour, do not penetrate fo far into them as the red, and others of a ftronger colour: but what this conftitution is, which is common to them all, deferves to be inquired into. For almoft all other tinctures, and this of lignum nephriticum too, after fome change made in it by Mr Boyle, as well as all other femi-tranfparent coloured fubftances, as glafs, appear of the fame hue in all pofitions of the eye. To increafe or diminifh the quantity makes no difference, but to make the colour deeper or more dilute.

29
Mr Boyle's account of the colours of thin plates.

The firft diftinct account of the colours exhibited by thin plates of various fubftances, are met with among the obfervations of Mr Boyle. To fhew the chemifts that colours may be made to appear or vanifh, where there is no acceffion or change either of the fulphureous, the faline, or the mercurial principle of bodies, he obferves, that all chemical effential oils, as

as alſo good ſpirit of wine, being ſhaken till they riſe in bubbles, appear of various colours; which immediately vaniſh when the bubbles burſt, ſo that a colourleſs liquor may be immediately made to exhibit a variety of colours, and loſe them in a moment, without any change in its eſſential principles. He then mentions the colours that appear in bubbles of ſoap and water, and alſo in turpentine. He ſometimes got glaſs blown ſo thin as to exhibit ſimilar colours; and obſerves, that a feather, of a proper ſhape and ſize, and alſo a black ribbon, held at a proper diſtance, between his eye and the ſun, ſhewed a variety of little rainbows, as he calls them, with very vivid colours, none of which were conſtantly to be ſeen in the ſame objects.

30 Dr Hooke's account of theſe colours.

Much more pains were taken with this ſubject, and a much greater number of obſervations reſpecting it were made, by Dr Hooke. As he loved to give ſurpriſe by his diſcoveries, he promiſed, at a meeting of the ſociety on the 7th of March 1672, to exhibit, at their next meeting, ſomething which had neither reflection nor refraction, and yet was diaphanous. Accordingly, at the time appointed, he produced the famous coloured bubble of ſoap and water, of which ſuch admirable uſe was afterwards made by Sir Iſaac Newton, but which Dr Hooke and his cotemporaries ſeem to have overlooked in Mr Boyle's treatiſe on colours, tho' it was publiſhed nine years before. It is no wonder that ſo curious an appearance excited the attention of that inquiſitive body, and that they ſhould deſire him to bring an account of it in writing at their next meeting.

By the help of a ſmall glaſs-pipe, there were blown ſeveral ſmall bubbles, out of a mixture of ſoap and water; where it was obſervable, that, at firſt, they appeared white and clear; but that, after ſome time, the film of water growing thinner, there appeared upon it all the colours of the rainbow: Firſt a pale yellow; then orange, red, purple, blue, green, &c. with the ſame ſeries of colours repeated; in which it was farther obſervable, that the firſt and laſt ſeries were very faint, and that the middlemoſt order or ſeries was very bright. After theſe colours had paſſed over the changes above mentioned, the film of the bubble began to appear white again; and preſently, in ſeveral parts of this ſecond white film, there appeared ſeveral holes, which by degrees grew very big, ſeveral of them running into one another. After reciting other obſervations, which are not of much conſequence, he ſays it is ſtrange, that tho' both the encompaſſing and encompaſſed air have ſurfaces, yet he could not obſerve that they afforded either reflection or refraction, which all the other parts of the encompaſſed air did. This experiment, he ſays, at firſt ſight, may appear very trivial, yet, as to the finding out the nature and cauſe of reflection, refraction, colours, congruity and incongruity, and ſeveral other properties of bodies, he looked upon it as one of the moſt inſtructive. And he promiſed to conſider it more afterwards; but we do not find that ever he did; nor indeed is it to be much regretted, as we ſhall ſoon find this buſineſs in better hands. He adds, that that which gives one colour by reflection, gives another by trajection; not much unlike the tincture of lignum nephriticum.

Dr Hooke was the firſt to obſerve, if not to deſcribe, the beautiful colours that appear in thin plates of muſcovy glaſs. Theſe, he ſays, are very beautiful to the naked eye, but much more when they are viewed with a microſcope. With this inſtrument he could perceive that theſe colours were ranged in rings ſurrounding the white ſpecks or flaws in this thin ſubſtance, that the order of the colours was the very ſame as in the rainbow, and that they were often repeated ten times. But the colours, he ſays, were diſpoſed as in the outer bow, and not the inner. Some of them alſo were much brighter than others, and ſome of them very much broader. He alſo obſerved, that if there was a place where the colours were very broad, and conſpicuous to the naked eye, they might be made, by preſſing the place with the finger, to change places, and move from one part to another. Laſtly, he obſerved, that if great care be uſed, this ſubſtance may be ſplit into plates of $\frac{1}{8}$ or $\frac{1}{6}$ of an inch in diameter, each of which will appear thro' a microſcope to be uniformly adorned with ſome one vivid colour, and that theſe plates will be found upon examination to be of the ſame thickneſs throughout.

As a fact ſimilar to this, but obſerved previous to it, we ſhall here mention that Lord Brereton, at a meeting of the Royal Society in 1666, produced ſome pieces of glaſs taken out of a window of a church, both on the north and on the ſouth ſide of it; obſerving, that they were all eaten in by the air, but that the piece taken from the ſouth ſide had ſome colours like thoſe of the rainbow upon it, which the others on the north ſide had not. This phenomenon has been frequently obſerved ſince, and in other circumſtances. It is not to doubted, but that in all theſe caſes, the glaſs is divided into thin plates, which exhibit colours, upon the ſame principle with thoſe which Dr Hooke obſerved in the bubble of ſoap and water, and in the thin plate of air, which we ſhall find more fully explained by Sir Iſaac Newton. With care the thin plates of the glaſs may be ſeparated, and the theory verified.

31 Why the ſtars are viſible by day at the bottom of a well.

An obſervation made by Otto Guericke, well explains the reaſon why ſtars are viſible at the bottom of a deep well. It is, ſays he, becauſe the light that proceeds from them is not overpowered by the rays of the ſun, which are loſt in the number of reflections which they muſt undergo in the pit, ſo that they can never reach the eye of a ſpectator at the bottom of it.

But of all thoſe who have given their attention to this ſubject of the reflection of light, none ſeems to have given ſuch ſatisfaction as M. Bouguer, and next to thoſe of Sir Iſaac Newton, his labours ſeem to have been the moſt ſucceſsful. The object of his curious and elaborate experiments was to meaſure the degrees of light, whether emitted, reflected, or refracted, by different bodies. They were originally occaſioned by an article of M. Mairan's in the Memoirs of the French academy for 1721, in which the proportion of the light of the ſun at the two ſolſtices were ſuppoſed to be known, and his laudable attempt to verify what had been before taken for granted, ſuggeſted a variety of new experiments, and opened to him and to the world a new field of optical knowledge. His firſt production upon this ſubject was a treatiſe intitled *Eſſai d'Optique*, which was received with general approbation. Afterwards,

wards, giving more attention to this ſubject, he formed an idea of a much larger work, to which many more experiments were neceſſary: but he was prevented, by a variety of interruptions, from executing his deſign ſo ſoon as he had propoſed; and he had hardly completed it at the time of his death, in 1758; ſo that we are obliged to his friend M. de la Caille for the care of the publication. At length, however, it was printed at Paris, in 1760, under the title of *Traite d' Optique*.

32 Diſcoveries of M. Bouguer.

At the entrance upon this treatiſe, we are induced to form the moſt pleaſing expectations from our author's experiments, by his account of the variety, the ſingular accuracy, and circumſpection, with which he made them; whereby he muſt, to all appearance, have guarded againſt every avenue to error, and particularly againſt thoſe objections to which the few attempts that had been made, of a ſimilar nature, before him had been liable. In order to compare different degrees of light, he always contrived to place the bodies from which it proceeded, or other bodies illuminated by them, in ſuch a manner as that he could view them diſtinctly at the ſame time; and he either varied the diſtances of theſe bodies, or modified their light in ſome other way, till he could perceive no difference between them. Then, conſidering their different diſtances, or the other circumſtances by which their light was affected, he calculated the proportion which they would have borne to each other at the ſame diſtance, or in the ſame circumſtances.

Plate CCVI fig. 3. To aſcertain the quantity of light loſt by reflection, he placed the mirror, or reflecting ſurface, B, on which the experiment was to be made, truly upright; and having taken two tablets, of preciſely the ſame colour, or of an equal degree of whiteneſs, he placed them exactly parallel to one another at E and D, and threw light upon them by means of a lamp or candle, P, placed in a right line between them. He then placed himſelf ſo that, with his eye at A, he could ſee the tablet E, and the image of the tablet D, reflected from the mirror B, at the ſame time; making them, as it were, to touch one another. He then moved the candle along the line ED, ſo as to throw more or leſs light upon either of them, till he could perceive no difference in the ſtrength of the light that came to his eye from them. After this, he had nothing more to do than to meaſure the diſtances EP and DP; for the ſquares of thoſe diſtances expreſſed the degree in which the reflection of the mirror diminiſhed the quantity of light. It is evident, that if the mirror reflected all the rays it received, the candle P muſt have been placed at C, at an equal diſtance from each of the tablets, in order to make them appear equally illuminated; but becauſe much of the light is loſt in reflection, they can only be made to appear equally bright by placing the candle nearer the tablet D, which is ſeen by reflection only.

Fig. 4. To find how much light is loſt by oblique reflection, he took two equally poliſhed plates, D and E, and cauſed them to be enlightened by the candle P; and while one of them, D, was ſeen at A, by reflection from B, placed in a poſition oblique to the eye, the other, E, was ſo placed, as to appear contiguous to it; and removing the plate E, till the light which it reflected was no ſtronger than that which came from the image D, ſeen by reflection at B, he eſtimated the quantity of light that was loſt by this oblique reflection, by the ſquares of the diſtances of the two objects from the candle.

It need ſcarcely be added, that, in theſe experiments all foreign light was excluded, that his eye was ſhaded, and that every other precaution was obſerved in order to make his concluſions unqueſtionable.

Fig. 5. In order to aſcertain the quantity of light loſt by reflection with the greateſt exactneſs, M. Bouguer introduced two beams of light into a darkened room, as by the apertures P and Q; which he had ſo contrived, that he could place them higher or lower, and enlarge or contract them at pleaſure; and the reflecting ſurface (as that of a fluid contained in a veſſel) was placed horizontally at O, from whence the light coming thro' the hole P, was reflected to R, upon the ſcreen GH, where it was compared with another beam of light that fell upon S, through the hole Q; which he made ſo much leſs than P, as that the ſpaces S and R were equally illuminated; and by the proportion that the apertures P and Q bore to each other, he calculated what quantity of light was loſt by the reflection at O.

It is neceſſary, he obſerves, that the two beams of light PO and QS (which he uſually made 7 or 8 feet long) ſhould be exactly parallel, that they might come from two points of the ſky equally elevated above the horizon, and having preciſely the ſame intenſity of light. It was alſo neceſſary that the hole Q ſhould be a little higher than P, in order that the two images ſhould be at the ſame height, and near one another. It is no leſs neceſſary, he ſays, that the ſcreen GH be exactly vertical, in order that the direct and reflected beams may fall upon it with the ſame inclination; ſince, otherwiſe, though the two lights were perfectly equal, they would not illuminate the ſcreen equally. This diſpoſition, he ſays, ſerves to anſwer another important condition in theſe experiments; for the direct ray QS muſt be of the ſame length with the ſum of the incident and reflected rays, PO and OR, in order that the quantity of light introduced into the room may be ſenſibly proportional to the ſizes of the apertures.

We ſhall now proceed to recite the reſult of the experiments which he made to meaſure the quantity of light that is loſt by reflection in a great variety of circumſtances; but we ſhall introduce them by the recital of ſome which were made previous to them on the diminution of light by reflection, and the tranſmiſſion of it to conſiderable diſtances through the air, by M. Buffon, at the time that he was conſtructing his machine to burn at great diſtances, mentioned under the article Burning-*Glaſs*.

33 Of Mr Buffon.

Receiving the light of the ſun in a dark place, and comparing it with the ſame light of the ſun reflected by a mirror, he found, that at ſmall diſtances, as four or five feet, about one half was loſt by reflection; as he judged by throwing two reflected beams upon the ſame place, and comparing them with a beam of direct light; for then the intenſity of them both ſeemed to be the ſame.

Having received the light at greater diſtances, as at 100, 200, and 300 feet, he could hardly perceive that it loſt any of its intenſity by being tranſmitted through ſuch a ſpace of air.

He afterwards made the ſame experiments with candles, in the following manner: He placed himſelf oppoſite

opposite to a looking-glass, with a book in his hand, in a room perfectly dark; and having one candle lighted in the next room, at the distance of about 40 feet, he had it brought nearer to him by degrees, till he was just able to distinguish the letters of the book, which was then 24 feet from the candle. He then received the light of the candle, reflected by the looking-glass, upon his book, carefully excluding all the light that was reflected from any thing else; and he found that the distance of the book from the candle, including the distance from the book to the looking-glass (which was only half a foot) was in all 15 feet. He repeated the experiment several times, and always with nearly the same result; and therefore concluded, that the quantity of direct light is to that of reflected as 576 to 225; so that the light of five candles reflected from a plane mirror is about equal to that of two candles.

From these experiments it appeared, that more light was lost by reflection of the candles than of the sun, which M. Buffon thought was owing to this circumstance, that the light issuing from the candle diverges, and therefore falls more obliquely upon the mirror than the light of the sun, the rays of which are nearly parallel.

These experiments and observations of M. Buffon are curious; though it will be seen that they fall far short of those of M. Bouguer, both in extent and accuracy. We shall begin with those which he made to ascertain the difference in the quantity of light reflected by glass and polished metal.

34 Mr Bouguer's discoveries concerning the reflection of glass and polished metal.

Using a smooth piece of glass one line in thickness, he found, that when it was placed at an angle 15 degrees with the incident rays, it reflected 628 parts of 1000 which fell upon it; at the same time that a metallic mirror, which he tried in the same circumstances, reflected only 561 of them. At a less angle of incidence much more light was reflected; so that at an angle of three degrees the glass reflected 700 parts, and the metal something less, as in the former case.

Trying the reflection of bodies that were not polished, he found that a piece of white plaster, placed at an angle of 75°, with the incident rays, reflected $\frac{1}{119}$ part of the light is received from a candle, nine inches from it. White paper, in the same circumstances, reflected in the same proportion; but at the distance of three inches, they both reflected 150 parts of 1000 that were incident.

Proceeding to make farther observations on the subject of reflected light, he premises the two following theorems, which he demonstrates geometrically. 1. When the luminous body is at an infinite distance, and its light is received by a globe, the surface of which has a perfect polish, and absorbs no light, it reflects the light equally in all directions, provided it be received at a considerable distance. He only excepts the place where the shadow of the globe falls; but this, he says, is no more than a single point, with respect to the immensity of the spherical surface which receives its light.

2. The quantity of light reflected in one certain direction will always be exactly the same, whether it be reflected by a very great number of small polished hemispheres, by a less number of larger hemispheres, or by a single hemisphere, provided they occupy the same base, or cover the same ground-plan.

The use he proposes to make of these theorems is to assist him in distinguishing whether the light reflected from bodies be owing to the extinction of it within them, or whether the roughness or eminences which cover them have not the same effect with the small polished hemispheres above-mentioned.

He begins with observing, that, of the light reflected from Mercury, $\frac{1}{4}$ at least is lost, and that probably no substances reflect more than this. The rays were received at an angle of $11\frac{1}{2}$ degrees of incidence, that is measured from the surface of the reflecting body, and not from the perpendicular, which, he says, is what we are from this place to understand whenever he mentions the angle of incidence.

35 Great differences in the reflective power of substances according to the angle of incidence.

The most striking observations which he made with respect to this subject, are those which relate to the very great difference in the quantity of light reflected at different angles of incidence. In general, he says, that reflection is stronger at small angles of incidence, and weaker at large ones. The difference is excessive when the rays strike the surface of transparent substances, with different degrees of obliquity; but it is almost as great in some opaque substances, and it was always more or less so in every thing that he tried. He found the greatest inequality in black marble; in which he was astonished to find, that, with an angle of 3° 35′ of incidence, though not perfectly polished, yet it reflected almost as well as quick-silver. Of 1000 rays which it received, it returned 600; but when the angle of incidence was 14 degrees, it reflected only 156; when it was 30, it reflected 51; and when it was 80, it reflected only 23.

Similar experiments made with metallic mirrors always gave the differences much less considerable. The greatest was hardly ever an eighth or a ninth part of it, but they were always in the same way.

The great difference between the quantity of light reflected from the surface of water, at different angles of incidence, is truly surprising; but our author observes, that this difference was greater when the smallest inclinations were compared with those which were near to a right angle. He sometimes suspected that, at very small angles of incidence, the reflection from water was even greater than from quick-silver. All things considered, he thought it was not quite so great, though it was very difficult to determine the precise difference between them. In very small angles, he says, that water reflects nearly $\frac{3}{4}$ of the direct light.

There is no person, he says, but has sometimes felt the force of this strong reflection from water, when he has been walking in still weather on the brink of a lake opposite to the sun. In this case, the reflected light is $\frac{1}{3}$, $\frac{1}{2}$, or sometimes a greater proportion of the light that comes directly from the sun, which is an addition to the direct rays of the sun that cannot fail to be very sensible. The direct light of the sun diminishes gradually as it approaches the horizon, while the reflected light at the same time grows stronger: so that there is a certain elevation of the sun, in which the united force of the direct and reflected light will be the greatest possible, and this he says is 12 or 13 degrees.

On the other hand, the light reflected from water at great angles of incidence is extremely small. Our author was assured, that, when the light was perpendicular, it reflected no more than the 37th part that quick-

quickfilver does in the fame circumftances; for it did not appear, from all his obfervations, that water reflects more than the 60th, or rather the 55th, part of perpendicular light. When the angle of incidence was 50 degrees, the light reflected from the furface of water was about the 32d part of that which mercury reflected; and as the reflection from water increafes with the diminution of the angle of incidence, it was twice as ftrong in proportion at 39 degrees; for it was then the 16th part of the quantity that mercury reflected.

In order to procure a common ftandard by which to meafure the proportion of light reflected from various fluid fubftances, he pitched upon water as the moft commodious; and partly by obfervation, and partly by calculation, which he always found to agree with his obfervations, he drew up the following table of the quantity of light reflected from the furface of water, at different angles with the furface.

Angles of incidence.	Rays reflected of 1000.	Angles of incidence.	Rays reflected of 1000.
$\frac{1}{2}$	721	17 $\frac{1}{2}$	178
1	692	20	145
1 $\frac{1}{2}$	669	25	97
2	639	30	65
2 $\frac{1}{2}$	614	40	34
5	501	50	22
7 $\frac{1}{2}$	409	60	19
10	333	70	18
12 $\frac{1}{2}$	271	80	18
15	211	90	18

In the fame manner, he drew up the following table, of the quantity of light reflected from the looking-glafs not quickfilvered.

Angles of incidence.	Rays reflected of 1000.	Angles of incidence.	Rays reflected of 1000.
2 $\frac{1}{2}$	584	30	112
5	543	40	57
7 $\frac{1}{2}$	474	50	34
10	412	60	27
12 $\frac{1}{2}$	356	70	25
15	299	80	25
20	222	90	25
25	157		

Pouring a quantity of water into a veffel containing quickfilver, it is evident that there will be two images of any objects feen by reflection from them, one at the furface of the water, and the other at that of the quickfilver. In the largeft angles of incidence, the image at the furface of the water will difappear, which will happen when it is about a 60th or an 80th part lefs luminous than the image at the furface of the quickfilver. Depreffing the eye, the image on the water will grow ftronger, and that on the quickfilver weaker in proportion; till at laft, the latter will be incomparably weaker than the former, and at an angle of about 10 degrees they will be equally luminous. According to the table, $\frac{333}{1000}$ of the incident rays are reflected from the water at this angle of 10 degrees. At the furface of the mercury, they were reduced to 500; and of thefe, part being reflected back upon it from the under furface of the water, only 333 remained to make the image from the mercury.

36 Reflection of images by the air.

It has been obferved by feveral perfons, particularly by Mr Edwards, (fee Phil. Tranf. vol. 53. p. 229.) that there is a remarkably ftrong reflection into water, with refpect to rays iffuing from the water; and perfons under water have feen images of things in the water in a manner peculiarly diftinct and beautiful: but this fact had not been obferved with a fufficient degree of attention, till it came into M. Bouguer's way to do it, and he acknowledges it to be very remarkable. In this cafe, he fays, that from the fmalleft angles of incidence, to a certain number of degrees, the greateft part of the rays are reflected, perhaps in as great a proportion as at the furface of metallic mirrors, or of quickfilver; while the other part, which does not efcape into the air, is extinguifhed or abforbed; fo that the furface of the tranfparent body appears opaque on the infide. If the angle of incidence be increafed only a few degrees, the ftrong reflection ceafes altogether, a great number of rays efcape into the air, and very few are abforbed or extinguifhed. In poportion as the angle of incidence is farther increafed, the quantity of the light reflected becomes lefs and lefs; and when it is near 90 degrees, almoft all the rays efcape out of the tranfparent body, its furface lofing almoft all its power of reflection, and becoming almoft as tranfparent as it is in other cafes, or when the light falls upon it from without.

37 Extinction of the rays of light at the furfaces of tranfparent bodies.

This property belonging to the furfaces of tranfparent bodies, of abforbing or extinguifhing the rays of light, is truly remarkable, and, as there is reafon to believe, had not been noticed by any perfon before M. Bouguer. It had been conjectured by Sir Ifaac Newton, that rays of light become extinct only by impinging upon the folid part of bodies; but thefe obfervations of M. Bouguer fhew that the fact is quite otherwife; and that this effect is to be attributed, not to the folid parts of bodies, which are certainly more numerous in a long tract of water than juft in the paffage out of water into air, but to fome power lodged at the furfaces of bodies only, and therefore probably the fame with that which reflects, refracts, and inflects the light.

38 Strong reflection by a prifm.

One of the above-mentioned obfervations, *viz.* all the light being reflected at certain angles of incidence from air into denfer fubftances, had frequently been obferved, efpecially in glafs prifms; fo that Newton made ufe of one of them inftead of a reflecting mirror, in the conftruction of his telefcope. If a beam of light fall upon the air from within thefe prifms, at an angle of 10, 20, or 30 degrees, the effect will be nearly the fame as at the furface of quickfilver, a fourth or a third of the rays being extinguifhed, and $\frac{2}{3}$ or $\frac{3}{4}$ths reflected. This property retains its full force as far as an incidence of 49° 49′, (fuppofing the proportion of the fines of refraction to be 31 and 20 for the mean refrangible rays); but if the angle of incidence be increafed but one degree, the quantity of light reflected inwards decreafes fuddenly, and a great part of the rays efcape out of the glafs, fo that the furface becomes fuddenly tranfparent.

All tranfparent bodies have the fame property, with this difference, that the angle of incidence at which the ftrong

ſtrong reflection ceaſes, and at which the light which is not reflected is extinguiſhed, is greater in ſome than in others. In water this angle is about 41° 32′; and in every medium it depends ſo much on the invariable proportion of the ſine of the angle of refraction to the ſine of the angle of incidence, that this law alone is ſufficient to determine all the phenomena of this new circumſtance, at leaſt as to this accidental opacity of the ſurface.

When our author proceeded to meaſure the quantity of light reflected by theſe internal ſurfaces at great angles of incidence, he found many difficulties, eſpecially on account of the many alterations which the light underwent before it came to his eye: but at length, uſing a plate of cryſtal, he found, that, at an angle of 75 degrees, this internal reflection diminiſhed the light 27 or 28 times; and as the external reflection at the ſame angle diminiſhed the light only 26 times, it follows that the internal reflection is a little ſtronger than the other.

Repeating theſe experiments with the ſame and different pieces of cryſtal, he ſometimes found the two reflections to be equally ſtrong; but, in general, the internal was the ſtronger. Alſo, the image reflected internally was always a little redder than an object which was ſeen directly through the plate of cryſtal.

39 Of the quantity of light reflected by different ſubſtances.

Reſuming his obſervations on the diminution of light, occaſioned by the reflection of opaque bodies obliquely ſituated, he compared it with the appearances of ſimilar ſubſtances which reflected the light perpendicularly. Uſing pieces of ſilver made very white, he found, that, when one of them was placed at an angle of 75 degrees with reſpect to the light, it reflected only 640 parts out of 1000. He then varied the angle, and alſo uſed white plaſter and fine Dutch paper, and drew up the following table of the proportion of the light reflected from each of thoſe ſubſtances at certain angles.

INTENSITY of LIGHT reflected from

Angles of incidence.	Silver.	Plaſter.	Dutch Paper.

Suppoſing the aſperities of opaque bodies to conſiſt of very ſmall planes, it appears from theſe obſervations, that there are fewer of them in theſe bodies which reflect the light at ſmall angles of incidence than at greater; and our author ſays, that the caſe was nearly the ſame with reſpect to all the opaque bodies that he tried. None of them had their roughneſs equivalent to ſmall hemiſpheres, which would have diſperſed the light equally in all directions; and, from the *data* in the preceding table, he deduces mathematically the number of the little planes that compoſe thoſe ſurfaces, and that are inclined to the general ſurface at the angles above-mentioned, ſuppoſing that the whole ſurface contains 1000 of them that are parallel to itſelf, ſo as to reflect the light perpendicularly, when the luminous body is ſituated at right angles with reſpect to it. His concluſions reduced to a table, correſponding to the preceding, are as follows:

Inclinations of the ſmall ſurfaces with reſpect to the large one.	The diſtribution of the ſmall planes that conſtitute the aſperities of the opaque ſurface in the

Theſe variations in the number of little planes, or ſurfaces, he expreſſes in the form of a curve; and afterwards he ſhews, geometrically, what would be the effect, if the bodies were enlightened in one direction, and viewed in another; upon which ſubject he has ſeveral curious theorems and problems: as, the poſition of the eye being given, to find the angle at which the luminous body muſt be placed, in order to its reflecting the moſt light; or, the ſituation of the luminous body being given, to find a proper ſituation for the eye, in order to ſee it the moſt enlightened, &c. But it would carry us too far into geometry to follow him through all theſe diſquiſitions.

Since the planets, as this accurate obſerver takes notice, are more luminous at their edges than at their centres, he concludes, from the abovementioned principles, that the bodies which form them are conſtituted in a manner different from ours; particularly that their opaque ſurfaces conſiſt of ſmall planes, more of which are inclined to the general ſurface than they are in terreſtrial ſubſtances; and that there are in them an infinity of points, which have exactly the ſame ſplendour. 40 Obſervations concerning the planets, &c.

Our philoſopher and geometrician next proceeds to aſcertain the quantity of ſurface occupied by the ſmall planes of each particular inclination, from conſidering the quantity of light reflected by each, allowing thoſe that have a greater inclination to the common ſurface to take up proportionably leſs ſpace than thoſe which are parallel to it. And comparing the quantity of light that would be reflected by ſmall planes thus diſpoſed, with the quantity of light that was actually reflected by the three ſubſtances abovementioned, he found, that plaſter, notwithſtanding its extreme whiteneſs, abſorbs much light; for that, of 1000 rays that fall upon it, of which 166 or 167 ought to be reflected at an angle of 77 degrees, only 67 are in fact returned; ſo that 100 out of 167 were extinguiſhed, that is, about three-fifths.

With reſpect to the planets, our author concludes, that of 300,000 rays which the moon receives, 172,000 are abſorbed, or perhaps 204,100.

Having conſidered the ſurfaces of bodies as conſiſting of planes only, he thus explains himſelf.—Each ſmall ſurface, ſeparately taken, is extremely irregular, and ſome of them are really concave, and others convex; but, in reducing them to a middle ſtate, they are to be conſidered as planes. Nevertheleſs he conſiders them 41 Of the ſurfaces of bodies.

them as planes only with respect to the reception of the rays; for as they are almost all curves, and as, besides this, many of those whose situation is different from others contribute to the same effect, the rays always issue from an actual or imaginary focus, and after reflection always diverge from one another.

If it be asked what becomes of those rays that are reflected from one asperity to another, he shews that very few of the rays can be in those circumstances; since they must fall upon planes which have more than 45 degrees of obliquity to the surface, of which there are very few in natural bodies. These rays must also fall at the bottom of those planes, and must meet with other planes similarly situated to receive them; and considering the great irregularity of the surfaces of opaque bodies, it may be concluded that very few of the rays are thus reflected upon the body itself; and that the little that is so reflected is probably lost to the spectators, being extinguished in the body.

42 Mr Melville's observations on the manner in which bodies are heated by light.

We are obliged to Mr Melville for some ingenious observations on the manner in which bodies are heated by light. He observes, that, as each colorific particle of an opaque body must be somewhat moved by the reaction of the particles of light, when it is reflected backwards and forwards between the same particles, it is manifest that they must likewise be agitated with a vibratory motion, and the time of a vibration will be equal to that which light takes up in moving from one particle of a body to another adjoining. This distance, in the most solid opaque bodies, cannot be supposed greater than $\frac{1}{12500}$th of an inch, which space a particle of light describes in the $\frac{1}{125000000000000}$th of a second. With so rapid a motion, therefore, may the internal parts of bodies be agitated by the influence of light, as to perform 125,000,000,000,000 vibrations, or more, in a second of time.

The arrival of different particles of light at the surface of the same colorific particle, in the same or different rays, may disturb the regularity of its vibrations, but will evidently increase their frequency, or raise still smaller vibrations among the parts which compose those particles; by which means the intestine motion will become more subtle, and more thoroughly diffused. If the quantity of light admitted into the body be increased, the vibrations of the particles must likewise increase in magnitude and velocity, till at last they may be so violent, as to make all the component particles dash one another to pieces by their mutual collision; in which case, the colour and texture of the body must be destroyed.

Since there is no reflection of light but at the surface of a medium, the same person observes, that the greatest quantity of rays, though crowded into the smallest space, will not of themselves produce any heat. From hence it follows, that the portion of air which lies in the focus of the most potent speculum, is not at all affected by the passage of light through it, but continues of the same temperature with the ambient air; though any opaque body, or even any transparent body denser than air, when put in the same place, would be intensely heated in an instant.

This consequence, evidently flowing from the plainest and most certain principles, not seeming to have been rightly understood by many philosophers; and even the silence of most physical writers concerning this paradoxical truth making it probable that they were unacquainted with it, he thought it worth his while to say something in explication of it. He observes, that the easiest way to be satisfied of the matter experimentally is, to hold a hair, or a piece of down, immediately above the focus of a lens or speculum, or to blow a stream of smoke from a pipe horizontally over it; for if the air in the focus were hotter than the surrounding fluid, it would continually ascend upon account of its rarefaction, and thereby sensibly agitate those slender bodies. Or a lens may be so placed as to form its focus within a body of water, or some other transparent substance, the heat of which may be examined from time to time with a thermometer; but care must be taken, in this experiment, to hold the lens as near as possible to the transparent body, lest the rays, by falling closer than ordinary on its surface, should warm it more than the common sunbeams.

To apply these observations to the explication of natural phenomena, he observes, that the atmosphere is not much warmed by the passage of the sun's light through it, but chiefly by its contact with the heated surface of the globe. This, he thought, furnished one very simple and plausible reason why it is coldest in all climates on the tops of very high mountains; namely, because they are removed to the greatest distance from the general surface of the earth. For it is well known, that a fluid heated by its contact with a solid body, decreases in heat in some inverse proportion to the distance from the body. He himself found, by repeated trials, that the heat of water in deep lakes decreases regularly from the surface downwards. But to have this question fully determined, the temperature of the air in the valley and on the mountain-top must be observed every hour, both night and day, and carefully compared together.

From this doctrine he thinks it reasonable to suppose, that the heat produced by a given number of rays, in an opaque body of a given magnitude, must be greater when the rays are more inclined to one another, than when they are less so; for the direction of the vibrations raised by the action of the light, whether in the colorific particles, or those of an inferior order, will more interfere with one another; from whence the intestine shocks and collisions must increase. Besides this, the colorific particles of opaque bodies being disposed in various situations, perhaps, upon the whole, the rays will fall more directly on each, the more they are inclined to one another. Is not this, says he, the reason of what has been remarked by philosophers, that the heat of the sun's light, collected into a cone, increases in approaching the focus in a much higher proportion than according to its density? That the difference of the angle in which the rays fall on any particle of a given magnitude, placed at different distances from the focus, is but small, is no proof that the phenomenon cannot be ascribed to it; since we know not in what high proportion one or both the circumstances now mentioned may operate. However, that it proceeds not from any unknown action of the rays upon one another, as has been insinuated, is evident from this, that each particular ray, after passing through the focus, preserves its own colour and its own direction, in the same manner

manner as if it were alone.

43 Abbé Nollet's experiments with burning-glasses.

The attempts of the Abbé Nollet to fire inflammable substances by the power of the solar rays collected in the foci of burning mirrors, have a near relation to the present subject. Considering the great power of burning mirrors and lenses, especially those of late construction, it will appear surprising that this celebrated experimental philosopher should not be able to fire any liquid substance. But though he made the trial with all the care imaginable on the 19th of February 1757, he was not able to do it either with spirit-of-wine, olive-oil, oil-of-turpentine, or æther; and though he could fire sulphur, yet he could not succeed with Spanish-wax, rosin, black pitch, or suet. He both threw the focus of these mirrors upon the substances themselves, and also upon the fumes that rose from them; but all the effect was, that the liquor boiled, and was dispersed in vapour or very small drops, but would not take fire. When linen-rags, and other solid substances, were moistened with any of these inflammable liquids, they would not take fire till the liquid was dispersed in a copious fume; so that rags thus prepared were longer in burning than those that were dry.

44 M. Beaume's experiments.

M. Beaume, who assisted M. Nollet in some of these experiments, observed farther, that the same substances which were easily fired by the flame of burning bodies, could not be set on fire by the contact of the hottest bodies that did not actually flame. Neither æther nor spirit-of-wine could be fired with a hot coal, or even red-hot iron, unless they were of a white heat. From these experiments our author concludes, that, supposing the electric matter to be the same thing with fire or light, it must fire spirit-of-wine by means of some other principle. The members of the academy Del Cimento had attempted to fire several of these substances, though without success; but this was so early in the history of philosophy, that nobody seems to have concluded, that, because they failed in this attempt, the thing could not be done. However, the Abbé informs us, that he read an account of his experiments to the Royal Academy at Paris several years before he attended to what had been done by the Italian philosophers.

45 Bodies which seem to touch one another are not actually in contact.

By the help of optical principles, and especially observations on the reflection of light, Mr Melville discovered that bodies which seem to touch one another are not always in actual contact. "It is common (says he) to admire the volubility and lustre of drops of rain that lie on the leaves of colewort, and some other vegetables;" but no philosopher, as far as he knew, had put himself to the trouble of explaining this curious phenomenon. Upon inspecting them narrowly, he found that the lustre of the drop is produced by a copious reflection of light from the flattened part of its surface contiguous to the plant. He observed farther, that, when the drop rolls along a part which has been wetted, it immediately loses all its lustre, the green plant being then seen clearly through it; whereas, in the other case, it is hardly to be discerned.

From these two observations put together, he concluded, that the drop does not really touch the plant, when it has the mercurial appearance, but is suspended in the air at some distance from it by the force of a repulsive power. For there could not be any copious reflection of white light from its under-surface, unless there were a real interval between it and the surface of the plant.

If that surface were perfectly smooth, the under-surface of the drop would be so likewise, and would therefore shew an image of the illuminating body by reflection, like a piece of polished silver; but as it is considerably rough and unequal, the under-surface becomes rough likewise, and so, by reflecting the light copiously in different directions, assumes the resplendent white colour of unpolished silver.

It being thus proved by an optical argument, that the drop is not really in contact with the plant which supports it, it may easily be conceived whence its volubility arises, and why it leaves no moisture where it rolls.

46 Two curious miscellaneous observations.

Before we conclude the history of the observations concerning the reflection of light, we must not omit to take notice of two curious miscellaneous ones. Baron Alexander Funk, visiting some silver-mines in Sweden, observed that, in a clear day, it was as dark as pitch under-ground in the eye of a pit, at 60 or 70 fathoms deep; whereas, in a cloudy or rainy day, he could even see to read at 106 fathoms deep. Inquiring of the miners, he was informed that this is always the case; and, reflecting upon it, he imagined that it arose from this circumstance, that when the atmosphere is full of clouds, light is reflected from them into the pit in all directions, and that thereby a considerable proportion of the rays are reflected perpendicularly upon the earth; whereas, when the atmosphere is clear, there are no opaque bodies to reflect the light in this manner, at least in a sufficient quantity; and rays from the sun itself can never fall perpendicularly in that country. The other was that of the ingenious Mr Grey, who makes such a figure in the history of electricity. This gentleman took a piece of stiff brown paper, and pricking a small hole in it, he held it at a little distance before him; when, applying a needle to his eye, he was surprised to see the point of it inverted. The nearer the needle was to the hole, the more it was magnified, but the less distinct; and if it was so held, as that its image was near the edge of the hole, its point seemed crooked. From these appearances he concluded, that these small holes, or something in them, produce the effects of concave speculums; and from this circumstance he took the liberty to call them *aërial speculums*.

§ 4. *Discoveries concerning the Inflection of Light.*

This property of light was not discovered till about the middle of the last century. The person who first made the discovery was Father Grimaldi; at least he first published an account of it in his treatise *De lumine, coloribus, et iride*, printed in 1666. Dr Hooke, however, laid claim to the same discovery, though he did not publish his observations till six years after Grimaldi; having probably never seen his performance.

47 Dr Hooke's discoveries.

Dr Hooke having made his room completely dark, admitted into it a beam of the sun's light by a very small hole in a brass plate fixed in the window-shutter. This beam spreading itself, formed a cone, the apex of which was in the hole, and the base was on a paper,

so placed, as to receive it at some distance. In this image of the sun, thus painted on the paper, he observed, that the middle was much brighter than the edges, and that there was a kind of dark penumbra about it, of about a 16th part of the diameter of the circle; which penumbra, he says, must be ascribed to a property of light, which he promised to explain.—Having observed this at the distance of about two inches from the former, he let in another cone of light; and receiving the bases of them, at such a distance from the holes as that the circles intersected each other, he observed that there was not only a penumbra, or darker ring, encompassing the lighter circle, but a manifest dark line, or circle, which appeared even where the limb of the one interfered with that of the other. This appearance is distinctly represented, Plate CCVI fig. 6.

Comparing the diameter of this base with its distance from the hole, he found it to be by no means the same as it would have been if it had been formed by straight lines drawn from the extremities of the sun's disk, but varied with the size of the holes, and the distance of the paper.

Struck with this appearance, he proceeded to make farther experiments concerning the nature of light thus transmitted. To give a just idea of which, he held an opaque body BB, fig. 7, so as to intercept the light that entered at a hole in the window-shutter O, and was received on the screen AP. In these circumstances, he observed, that the shadow of the opaque body (which was a round piece of wood, not bright or polished) was all over somewhat enlightened, but more especially towards the edge. Some persons who were present, imagining that this light within the shadow might be produced by some kind of reflection from the side of this opaque body, on account of its roundness; and others supposing it might proceed from some reflection from the sides of the hole in the piece of brass through which the light was admitted into the room; to obviate both these objections, he admitted the light through a hole burnt in a piece of pasteboard, and intercepted it with a razor which had a very sharp edge; but still the appearances were the very same as before: so that, upon the whole, he concluded that they were occasioned by a new property of light, different from any that had been observed by preceding writers.

He farther diversified this experiment, by placing the razor so as to divide the cone of light into two parts, the hole in the shutter remaining as before, and placing the paper so as that none of the enlightened part of the circle fell upon it, but only the shadow of the razor; and, to his great surprise, he observed what he calls a *very brisk and visible radiation* striking down upon the paper, of the same breadth with the diameter of the lucid circle; and this radiation always struck perpendicularly from the line of shadow, and, like the tail of a comet, extended more than 10 times, and probably more than 100 times the breadth of the remaining part of the circle: nay, as far as he could find, by many trials, the light from the edge struck downwards into the shadow very near to a quadrant, though the greater were the deflections of this new light from the direct radiations of the cone, the more faint they were.

Observing this appearance with more attention, he found, wherever there was a part of the interposed body higher than the rest, that, opposite to it, the radiation of light into the shadow was brighter, as in the figure; and wherever there was a notch or gap in it, there would be a dark stroke in the half-enlightened shadow. From all these appearances, he concluded that they were to be ascribed to a new property of light, whereby it is deflected from straight lines, contrary to what had been before asserted by optical writers.

It does not appear, however, that our philosopher ever prosecuted this experiment to any purpose; as all that we find of his on the subject of light, after this time, are some crude thoughts which he read at a meeting of the Royal Society, on the 18th of March 1675; which, however, as they are only short hints, we shall copy.

They consist of eight articles; and, as he thought, contained an account of several properties of light, that had not been noticed before. There is a deflection of light, differing both from reflection and refraction, and seeming to depend on the unequal density of the constituent parts of the ray, whereby the light is dispersed from the place of condensation, and rarified, or gradually diverged into a quadrant. 2. This deflection is made towards the superficies of the opaque body perpendicularly. 3. Those parts of the diverged radiations which are deflected by the greatest angle from the straight or direct radiations are the faintest, and those that are deflected by the least angles are the strongest. 4. Rays cutting each other in one common foramen do not make the angles at the vertex equal. 5. Colours may be made without refraction. 6. The diameter of the sun cannot be truly taken with common sights. 7. The same rays of light, falling upon the same point of an object, will turn into all sorts of colours, by the various inclination of the object. 8. Colours begin to appear when two pulses of light are blended so well, and so near together, that the sense takes them for one.

48 Grimaldi's discoveries.

We shall now proceed to the discoveries of Father Grimaldi. Having introduced a ray of light, through a very small hole, AB, fig. 8. into a darkened room, he observed that the light was diffused in the form of a cone, the base of which was CD; and that if any opaque body, FE, was placed in this cone of light, at a considerable distance from the hole, and the shadow was received upon a piece of white paper, the boundaries of it were not confined within GH, or the penumbra IL, occasioned by the light proceeding from different parts of the aperture, and of the disk of the sun, but extended to MN; at which he was very much surprised, suspecting, and finding by calculation, that it was considerably broader than it could have been made by rays passing in right lines by the edges of the object.

But the most remarkable circumstance in this appearance was, that upon the lucid part of the base, CM and ND, streaks of coloured light were plainly distinguished, each being terminated by blue on the side next to the shadow, and by red on the other; and though these coloured streaks depended, in some measure, on the size of the aperture AB, because they could not be made to appear if it was large, yet he

A. Bell Sculp.

he found that they were not limited either by it, or by the diameter of the ſun's diſk.

He farther obſerved, that theſe coloured ſtreaks were not all of the ſame breadth, but grew narrower as they receded from the ſhadow, and were each of them broader the farther the ſhadow was received from the opaque body, and alſo the more obliquely the paper on which they were received was held with reſpect to it. He never obſerved more than three of theſe ſtreaks.

To give a clearer idea of theſe coloured ſtreaks, he drew the repreſentation of them, exhibited in fig. 9. in which NMO repreſents the broadeſt and moſt luminous ſtreak, next to the dark ſhadow X. In the ſpace in which M is placed there was no diſtinction of colour, but the ſpace NN was blue, and the ſpace OO, on the other ſide of it, was red. The ſecond ſtreak, QPR, was narrower than the former; and of the three parts of which it conſiſted, the ſpace P had no particular colour, but QQ was a faint blue, and RR a faint red. The third ſtreak, TSV, was exactly ſimilar to the two others, but narrower than either of them, and the colours ſtill fainter.

Theſe coloured ſtreaks he obſerved to lie parallel to the ſhadow of the opaque body; but when it was of an angular form, they did not make the ſame acute angles, but were bent into a curve, the outermoſt being rounder than thoſe that were next the ſhadow, as is repreſented in fig. 10. If it was an inward angle, as DCH, the coloured ſtreaks, parallel to each other of the two ſides, croſſed without obliterating one another; only the colours were thereby rendered either more intenſe, or mixed.

The light that formed theſe coloured ſtreaks, the reader will perceive, muſt have been bent from the body; but this attentive obſerver has likewiſe given an account of other appearances, which muſt have been produced by the light bending towards the body. For within the ſhadow itſelf he ſometimes perceived coloured ſtreaks, ſimilar to thoſe above-mentioned on the outſide of the ſhadow. Sometimes he ſaw more of them, and ſometimes fewer: but for this purpoſe a very ſtrong light was requiſite, and the opaque body was obliged to be long, and of a moderate breadth; which, he ſays, is eaſily found by experience. A hair, for inſtance, or a fine needle, did not anſwer ſo well as a thin and narrow plate; and the ſtreaks were moſt diſtinguiſhable when the ſhadow was taken at the greateſt diſtance; but then the light grew fainter in the ſame proportion.

The number of theſe ſtreaks within the ſhadow was greater in proportion to the breadth of the plate. They were at leaſt two, and ſometimes four, if a thicker rod were made uſe of. But, with the ſame plate or rod, more or fewer ſtreaks appeared, in proportion to the diſtance at which the ſhadow was received; but they were broader when they were few, and narrower when there were more of them; and they were all much more diſtinct when the paper was held obliquely.

Theſe coloured ſtreaks within the ſhadow, like thoſe on the outſide of it, were bent in an arch, round the acute angles of the ſhadow, as they are repreſented in fig. 11. At this angle alſo, as at D, other ſhorter lucid ſtreaks were viſible, bent in the form of a plume, as they are drawn betwixt D and C, each bending round and meeting again in D. Theſe angular ſtreaks appeared, though the plate or rod was not wholly immerſed in the beam of light, but the angle of it only; and there were more or fewer in number, in proportion to the breadth of the rod or plate. If the plate or rod was very thin, the coloured ſtreaks within the ſhadow might be ſeen to bend round from the oppoſite ſides, and meet one another, as at B. A only repreſents a ſection of the figure, and not a proper termination of the ſhadow, and the ſtreaks within each ſide of it. The coloured ſtreaks without the ſhadow, he alſo obſerves, bend round it in the ſame manner.

Our author acknowledges, that he omits ſeveral obſervations of leſs conſequence, which cannot but occur to any perſon who ſhall make the experiment; and he ſays, that he was not able to give a perfectly clear idea of what he has attempted to deſcribe, nor does he think it in the power of words to do it.

In order to obtain the more ſatisfactory proof that rays of light do not always proceed in ſtraight lines, but really bend, in paſſing by the edges of bodies, he diverſified the firſt of the above-mentioned experiments in the following manner. He admitted a beam of light, by a very ſmall aperture, into a darkened room, as before; and, at a great diſtance from it, he fixed a plate EF, fig. 12. with a ſmall aperture, GH, which admitted only a part of the beam of light, and found, that when the light tranſmitted through this plate, was received at ſome diſtance, upon a white paper, the baſe IK was conſiderably larger than it could poſſibly have been made by rays iſſuing in the light lines through the two apertures, as the other ſtraight lines drawn cloſe to their edges plainly demonſtrate.

That thoſe who chooſe to repeat theſe experiments may not be diſappointed in their expectations from them, our author gives the following more particular inſtructions. The ſun's light muſt be very intenſe, and the apertures through which it is tranſmitted very narrow, particularly the firſt, CD, and the white paper, IK, on which it is received, muſt be at a conſiderable diſtance from the hole GH; otherwiſe it will not much exceed NO, which would be the breadth of the beam of light proceeding in ſtraight lines. He generally made the aperture CD $\frac{4}{100}$ or $\frac{5}{100}$ part of an ancient Roman foot, and the ſecond aperture, GH, $\frac{25}{100}$ or $\frac{30}{100}$; and the diſtances DG and GN were, at leaſt, 12 ſuch feet. The obſervation was made in the ſummer-time, when the atmoſphere was free from all vapours, and about mid-day.

F. Grimaldi alſo made the ſame experiment that has been recited from Dr Hooke, in which two beams of light, entering a darkened room by two ſmall apertures near to one another, projected cones of light, which, at a certain diſtance, in part coincided; and he particularly obſerved that the dark boundaries of each of them were viſible within the lucid ground of the other.

49 Obſervation of Dechales

To theſe diſcoveries of Grimaldi, we ſhall ſubjoin an additional obſervation of Dechales; who took notice, that if ſmall ſcratches be made in any piece of poliſhed metal, and it be expoſed to the beams of the ſun in a darkened room, it will reflect the rays ſtreaked with colours in the direction of the ſcratches;

ches; as will appear if the reflected light be received upon a piece of white paper. That theſe colours are not produced by refraction, he ſays, is manifeſt; for that, if the ſcratches be made upon glaſs, the effect will be the ſame; and in this caſe, if the light had been refracted at the ſurface of the glaſs, it would have been tranſmitted through it. From theſe, and many other obſervations, he concludes that colour does not depend upon the refraction of light only, nor upon a variety of other circumſtances, which he particularly enumerates, and the effects of which he diſcuſſes, but upon the intenſity of the light only.

50 Of M. De la Hire.

We ſhall here give an account of a phenomenon of viſion obſerved by M. De la Hire, becauſe the ſubject of this ſection, viz. the *inflection of light*, ſeems to ſupply the true ſolution of it, though the author himſelf thought otherwiſe. It is obſervable, he ſays, that when we look at a candle, or any luminous body, with our eyes nearly ſhut, rays of light are extended from it, in ſeveral directions, to a conſiderable diſtance, like the tails of comets. This appearance exerciſed the ſagacity of Deſcartes and Rohault, as well as of our author; but all three ſeem to have been miſtaken with reſpect to it. Deſcartes aſcribed this effect to certain wrinkles in the ſurface of the humours of the eye. Rohault ſays, that when the eye-lids are nearly cloſed, the edges of them act like convex lenſes. But our author ſays, that the moiſture on the ſurface of the eye, adhering partly to the eye itſelf, and partly to the edge of the eye-lid, makes a concave mirror, and ſo diſperſes the rays at their entrance into the eye. But the true reaſon ſeems to be, that the light paſſing among the eye-laſhes, in this ſituation of the eye, is inflected by its near approach to them, and therefore enters the eye in a great variety of directions. The two former of theſe opinions are particularly ſtated and objected to by our author.

51 Sir Iſaac Newton's diſcoveries.

The experiments of Father Grimaldi and Dr Hooke were not only repeated with the greateſt care by Sir Iſaac Newton, but carried much farther than they had thought of. So little uſe had been made of Grimaldi's obſervations, that all philoſophers before Newton had aſcribed the broad ſhadows, and even the fringes of light which he deſcribed, to the ordinary refraction of the air; but we ſhall ſee them placed in a very different point of view by our author.

He made in a piece of lead a ſmall hole with a pin, the breadth of which was the 42d part of an inch, Through this hole he let into his darkened chamber a beam of the ſun's light; and found, that the ſhadows of hairs, and other ſlender ſubſtances placed in it, were conſiderably broader than they would have been, if the rays of light had paſſed by thoſe bodies in right lines. He therefore concluded, that they muſt have paſſed as they are repreſented in fig. 1. in which X repreſents a ſection of the hair, and AD, BE, &c. rays of light paſſing by at different diſtances, and then falling upon the wall GQ. Since, when the paper which receives the rays is at a great diſtance from the hair, the ſhadow is broad, it muſt follow, as he obſerves, that the hair acts upon the rays of light at ſome conſiderable diſtance from it, the action being ſtrongeſt on thoſe rays which are at the leaſt diſtance, and growing weaker and weaker on thoſe which are farther off, as is repreſented in this figure; and from hence it came to paſs, that the ſhadow of the hair is much broader in proportion to the diſtance of the paper from the hair when it is nearer than when it is at a great diſtance.

Plate CCVII.

He found, that it was not material whether the hair was ſurrounded with air, or with any other pellucid ſubſtance; for he wetted a poliſhed plate of glaſs, and laid the hair in the water upon the glaſs, and then laying another poliſhed plate of glaſs upon it, ſo that the water might fill up the ſpace between the glaſſes, and holding them in the beam of light, he found the ſhadow at the ſame diſtances was as big as before. Alſo the ſhadows of ſcratches made in poliſhed plates of glaſs, and the veins in the glaſs, caſt the like broad ſhadows; ſo that this breadth of ſhadow muſt proceed from ſome other cauſe than the refraction of the air.

The ſhadows of all bodies, metals, ſtones, glaſs, wood, horn, ice, &c. in this light were bordered with three parallel fringes, or bands of coloured light, of which that which was contiguous to the ſhadow was the broadeſt and moſt luminous, while that which was the moſt remote was the narroweſt, and ſo faint as not eaſily to be viſible. It was difficult to diſtinguiſh theſe colours, unleſs when the light fell very obliquely upon a ſmooth paper, or ſome other ſmooth white body, ſo as to make them appear much broader than they would otherwiſe have done; but in theſe circumſtances the colours were plainly viſible, and in the following order. The firſt or innermoſt fringe was violet, and deep blue next the ſhadow, light blue, green, and yellow in the middle, and red without. The ſecond fringe was almoſt contiguous to the firſt, and the third to the ſecond; and both were blue within, and yellow and red without; but their colours were very faint, eſpecially thoſe of the third. The colours, therefore, proceeded in the following order from the ſhadow; violet, indigo, pale blue, green, yellow, red; blue, yellow, red; pale blue, pale yellow, and red. The ſhadows made by ſcratches and bubbles in poliſhed plates of glaſs were bordered with the like fringes of coloured light.

He alſo obſerves, that by looking on the ſun thro' a feather, or black ribbon, held cloſe to the eye, ſeveral rainbows will appear, the ſhadows which the fibres or threads caſt on the retina being bordered with the like fringes of colours.

Meaſuring theſe fringes and their intervals with the greateſt accuracy, he found the former to be in the progreſſion of the numbers 1, $\sqrt{\frac{1}{3}}$, $\sqrt{\frac{1}{5}}$, and their intervals to be in the ſame progreſſion with them, that is, the fringes and their intervals together to be in continual progreſſion of the numbers 1, $\sqrt{\frac{1}{2}}$, $\sqrt{\frac{1}{3}}$, $\sqrt{\frac{1}{4}}$, $\sqrt{\frac{1}{4}}$, or thereabouts. And theſe proportions held the ſame very nearly at all diſtances from the hair, the dark intervals of the fringes being as broad in proportion to the breadth the fringes at their firſt appearance as afterwards, at great diſtances from the hair, though not ſo dark and diſtinct.

In the next obſervation of our author, we find a very remarkable and curious appearance, which we ſhould hardly have expected from the circumſtances, though it is pretty ſimilar to one that was noticed by Dr Hooke. The ſun ſhining into his darkened chamber, through a hole $\frac{1}{4}$ of an inch broad, he placed, at the diſtance of two or three feet from the hole, a ſheet of paſteboard,

board, black on both ſides; and in the middle of it he had made a hole about $\frac{1}{4}$ of an inch ſquare, for the light to paſs through; and behind the hole he faſtened to the paſteboard the blade of a ſharp knife, to intercept ſome part of the light which paſſed thro' the hole. The planes of the paſteboard and blade of the knife were parallel to one another, and perpendicular to the rays; and when they were ſo placed that none of the light fell on the paſteboard, but all of it paſſed through the hole to the knife, and there part of it fell upon the blade of the knife, and part of it paſſed by its edge, he let that part of the light which paſſed by fall on a white paper, 2 or 3 feet beyond the knife, and there ſaw two ſtreams of faint light ſhoot out both ways from the beam of light into the ſhadow, like the tails of comets. But becauſe the ſun's direct light, by its brightneſs upon the paper, obſcured theſe faint ſtreams, ſo that he could ſcarce ſee them, he made a little hole in the midſt of the paper for that light to paſs through and fall on a black cloth behind it; and then he ſaw the two ſtreams plainly. They were like one another, and pretty nearly equal in length, breadth, and quantity of light. Their light, at that end which was next to the ſun's direct light, was pretty ſtrong for the ſpace of about $\frac{1}{4}$ of an inch, or $\frac{1}{2}$ of an inch, and decreaſed gradually till it became inſenſible.

The whole length of either of theſe ſtreams, meaſured upon the paper, at the diſtance of 3 feet from the knife, was about 6 or 8 inches; ſo that it ſubtended an angle, at the edge of the knife, of about 10 or 12, or at moſt 14 degrees. Yet ſometimes he thought he ſaw it ſhoot 3 or 4 degrees farther; but with a light ſo very faint, that he could hardly perceive it. This light he ſuſpected might, in part at leaſt, ariſe from ſome other cauſe than the two ſtreams. For, placing his eye in that light, beyond the end of that ſtream which was behind the knife, and looking towards the knife, he could ſee a line of light upon its edge; and that not only when his eye was in the line of the ſtreams, but alſo when it was out of that line, either towards the point of the knife, or towards the handle. This line of light appeared contiguous to the edge of the knife, and was narrower than the light of the innermoſt fringe, and narroweſt when his eye was fartheſt from the direct light; and therefore ſeemed to paſs between the light of that fringe and the edge of the knife; and that which paſſed neareſt the edge ſeemed to be moſt bent, though not all of it.

He then placed another knife by the former, ſo that their edges might be parallel, and look towards one another, and that the beam of light might fall upon both the knives, and ſome part of it paſs between their edges. In this ſituation he obſerved, that when the diſtance of their edges was about the 400th part of an inch, the ſtream divided in the middle, and left a ſhadow between the two parts. This ſhadow was ſo black and dark, that all the light which paſſed between the knives ſeemed to be bent and turned aſide to the one hand or the other; and as the knives ſtill approached one another, the ſhadow grew broader, and the ſtreams ſhorter, next to it, till, upon the contact of the knives, all the light vaniſhed.

From this experiment our author concludes, that the light which is leaſt bent, and which goes to the inward ends of the ſtreams, paſſes by the edges of the knives at the greateſt diſtance; and this diſtance, when the ſhadow began to appear between the ſtreams, was about the 800th part of an inch; and the light which paſſed by the edges of the knives at diſtances ſtill leſs and leſs, was more and more faint, and went to thoſe parts of the ſtreams which were farther from the direct light; becauſe, when the knives approached one another till they touched, thoſe parts of the ſtreams vaniſhed laſt which were fartheſt from the direct light.

In the experiment of one knife only, the coloured fringes did not appear; but, on account of the breadth of the hole in the window, became ſo broad as to run into one another, and, by joining, to make one continual light in the beginning of the ſtreams; but in the laſt experiment, as the knives approached one another, a little before the ſhadow appeared between the two ſtreams, the fringes began to appear on the inner ends of the ſtreams, on either ſide of the direct light, three on one ſide, made by the edge of one knife, and three on the other ſide, made by the edge of the other knife. They were the moſt diſtinct when the knives were placed at the greateſt diſtance from the hole in the window, and became ſtill more diſtinct by making the hole leſs; ſo that he could ſometimes ſee a faint trace of a 4th fringe, beyond the three abovementioned; and as the knives approached one another, the fringes grew more diſtinct and larger, till they vaniſhed; the outermoſt vaniſhing firſt, and the innermoſt laſt. After they were all vaniſhed, and the line of light which was in the middle between them was grown very broad, extending itſelf on both ſides into the ſtreams of light deſcribed before, the above-mentioned ſhadow began to appear in the middle of this line, and to divide it along the middle into two lines of light, and increaſed till all the light vaniſhed. This enlargement of the fringes was ſo great, that the rays which went to the innermoſt fringe ſeemed to be bent about 20 times more when the fringe was ready to vaniſh, than when one of the knives was taken away.

From both theſe experiments compared together, our author concluded, that the light of the firſt fringe paſſed by the edge of the knife at a diſtance greater than the 800th part of an inch, that the light of the ſecond fringe paſſed by the edge of the knife at a greater diſtance than the light of the firſt fringe, and that of the third at a greater diſtance than that of the ſecond; and that the light of which the ſtreams abovementioned conſiſted, paſſed by the edges of the knives at leſs diſtances than that of any of the fringes.

He then got the edges of two knives ground truly ſtraight, and pricking their points into a board, ſo that their edges might look towards one another, and meeting near their points, contain a rectilinear angle, he faſtened their handles together, to make the angle invariable. The diſtance of the edges of the knives from one another, at the diſtance of 4 inches from the angular point, where the edges of the knives met, was the 8th part of an inch, ſo that the angle contained by their edges was about $1^{\circ}\ 54'$. The knives being thus fixed together, he placed them in a beam of the ſun's light let into his darkened chamber, thro' a hole the 42d part of an inch wide, at the diſtance of 10 or 13 feet from the hole; and he let the light which paſſed between their edges fall very obliquely on a ſmooth

ſmooth white ruler, at the diſtance of $\frac{1}{2}$ inch, or an inch, from the knives; and there he ſaw the fringes made by the two edges of the knives run along the edges of the ſhadows of the knives, in lines parallel to thoſe edges, without growing ſenſibly broader, till they meet in angles equal to the angle contained by the edges of the knives; and where they met and joined they ended, without croſſing one another. But if the ruler was held at a much greater diſtance from the knives, the fringes, where they were farther from the place of their meeting, were a little narrower, and they became ſomething broader as they approached nearer to one another, and after they met they croſſed one another, and then became much broader than before.

From theſe obſervations he concluded, that the diſtances at which the light compoſing the fringes paſſed by the knives were not increaſed or altered by the approach of the knives, but that the angles in which the rays were there bent were much increaſed by that approach, and that the knife which was neareſt to any ray determined which way the ray ſhould be bent, but that the other knife increaſed the bending.

When the rays fell very obliquely upon the ruler, at the diſtance of a third part of an inch from the knives, the dark line between the firſt and ſecond fringe of the ſhadow of one knife, and the dark line between the firſt and ſecond fringe of the ſhadow of the other knife, met one another, at the diſtance of the fifth part of an inch from the end of the light which paſſed between the knives, where their edges met one another; ſo that the diſtance of the edges of the knives, at the meeting of the dark lines, was the 160th part of an inch; and one half of that light paſſed by the edge of one knife, at a diſtance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the ſhadow of that knife; while the other half paſſed by the edge of the other knife, at a diſtance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the ſhadow of the other knife. But if the paper was held at a diſtance from the knives greater than the third part of an inch, the dark lines above-mentioned met at a greater diſtance than the fifth part of an inch from the end of the light which paſſed between the knives, at the meeting of their edges; ſo that the light which fell upon the paper where thoſe dark lines met paſſed between the knives, where their edges were farther diſtant than the 160th part of an inch. For at another time, when the two knives were 8 feet and 5 inches from the little hole in the window, the light which fell upon the paper where the above-mentioned dark lines met paſſed between the knives, where the diſtance between their edges was, as in the following table, at the diſtances from the paper there noted.

Diſtances of the paper from the knives in inches.	Diſtances between the edges of the knives in milleſimal parts of an inch.
$1\frac{1}{2}$	0,012
$3\frac{1}{3}$	0,020
$8\frac{3}{5}$	0,034
32	0,057
96	0,081
131	0,087

From theſe obſervations he concluded, that the light which makes the fringes upon the paper is not the ſame light at all diſtances of the paper from the knives; but that, when the paper is held near the knives, the fringes are made by light which paſſes by the edges of the knives at a leſs diſtance, and is more bent than when the paper is held at a greater diſtance from the knives.

When the fringes of the ſhadows of the knives fell perpendicularly upon the paper, at a great diſtance from the knives, they were in the form of hyperbolas, their dimenſions being as follows. Let CA, CB, repreſent lines drawn upon the paper, parallel to the edges of the knives; and between which all the light would fall if it ſuffered no inflection. DE is a right line drawn through C, making the angles ACD, BCE, equal to one another, and terminating all the light which falls upon the paper, from the point where the edges of the knives meet. Then *eis*, *fkt*, and *glv*, will be three hyperbolical lines, repreſenting the boundaries of the ſhadow of one of the knives, the dark line between the firſt and ſecond fringes of that ſhadow, and the dark line between the ſecond and third fringes of the ſame ſhadow. Alſo *xip*, *ykq*, and *zlr*, will be three other hyperbolical lines, repreſenting the boundaries of the ſhadow of the other knife, the dark line between the firſt and ſecond fringes of that ſhadow, and the dark line between the ſecond and third fringes of the ſame ſhadow. Theſe three hyperbolas are ſimilar, and equal to the former three, and croſs them in the points *i*, *k*, and *l*; ſo that the ſhadows of the knives are terminated, and diſtinguiſhed from the firſt luminous fringes, by the lines *eis* and *xip*, till the meeting and croſſing of the fringes; and then thoſe lines croſs the fringes in the form of dark lines terminating the firſt luminous fringes on the inſide, and diſtinguiſhing them from another light, which begins to appear at *i*, and illuminates all the triangular ſpace *ip* DE*s*, comprehended by theſe dark lines and the right line DE. Of theſe hyperbolas one aſymptote is the line DE, and the other aſymptotes are parallel to the lines CA and CB. Plate CCVII. fig. 2.

The ſun ſhining into his darkened room through the ſmall hole mentioned above, he placed at the hole a priſm to refract the light, and to form on the oppoſite wall the coloured image of the ſun; and he found, that the ſhadows of all bodies held in the coloured light between the priſm and the wall, were bordered with fringes of the colour of that light in which they were held; and comparing the fringes made in the ſeveral coloured lights, he found, that thoſe made in the red light were the largeſt, thoſe made in the violet were the leaſt, and thoſe made in the green were of a middle bigneſs. For the fringes with which the ſhadow of a man's hair were bordered, being meaſured croſs the ſhadow, at the diſtance of ſix inches from the hair, the diſtance between the middle and moſt luminous part of the firſt or innermoſt fringe on one ſide of the ſhadow, and that of the like fringe on the other ſide of the ſhadow, was, in the full red light $\frac{1}{37\frac{1}{2}}$ of an inch, and in the full violet $\frac{1}{46}$. The like diſtance between the middle and moſt luminous parts of the ſecond fringes, on either ſide of the ſhadow, was in the full red light $\frac{1}{22}$, and the violet $\frac{1}{27}$ of an inch; and theſe diſtances of the fringes held the ſame proportion

portion at all diſtances from the hair, without any ſenſible variation.

From theſe obſervations it was evident, that the rays which made the fringes in the red light, paſſed by the hair at a greater diſtance than thoſe which made the like fringes in the violet; ſo that the hair, in cauſing theſe fringes, acted alike upon the red light or leaſt refrangible rays at a greater diſtance, and upon the violet or moſt refrangible rays at a leſs diſtance; and thereby occaſioned fringes of different ſizes, without any change in the colour of any ſort of light.

It may therefore be concluded, that when the hair in the firſt obſervation was held in the white beam of the ſun's light, and caſt a ſhadow which was bordered with three fringes of coloured light, thoſe colours aroſe not from any new modifications impreſſed upon the rays of light by the hair, but only from the various inflections whereby the ſeveral ſorts of rays were ſeparated from one another, which before ſeparation, by the mixture of all their colours, compoſed the white beam of the ſun's light; but, when ſeparated, compoſed lights of the ſeveral colours which they are originally diſpoſed to exhibit.

52 Maraldi's diſcoveries. The perſon whoſe name we find firſt upon the liſt of thoſe who purſued any experiments ſimilar to thoſe of Newton on inflected light is M. Maraldi; whoſe obſervations chiefly reſpect the inflection of light towards other bodies, whereby their ſhadows are partially illuminated; and many of the circumſtances which he noticed relating to it are well worthy of our attention, as the reader will be convinced from the following account of them.

53 Experiments concerning the ſhadows of cylinders. He expoſed in the light of the ſun a cylinder of wood three feet long, and $6\frac{1}{2}$ lines in diameter; when its ſhadow, being received upon a paper held cloſe to it, was every where equally black and well defined, and continued to be ſo to the diſtance of 23 inches from it. At a greater diſtance the ſhadow appeared to be of two different denſities; for the two extremities of the ſhadow, in the direction of the length of the cylinder, were terminated by two dark ſtrokes, a little more than a line in breadth. Within theſe dark lines there was a faint light, equally diſperſed through the ſhadow, which formed an uniform penumbra, much lighter than the dark ſtrokes at the extremity, or than the ſhadow received near the cylinder. This appearance is repreſented in Plate CCVII. fig. 3.

As the cylinder was removed to a greater diſtance from the paper, the two black lines continued to be nearly of the ſame breadth, and the ſame degree of obſcurity; but the penumbra in the middle grew lighter, and its breadth diminiſhed, ſo that the two dark lines at the extremity of the ſhadow approached one another, till, at the diſtance of 60 inches, they coincided, and the penumbra in the middle entirely vaniſhed. At a ſtill greater diſtance a faint penumbra was viſible, but it was ill defined, and grew broader as the cylinder was removed farther off, but was ſenſible at a very great diſtance.

Beſides the black and dark ſhadow, which the cylinder formed near the opaque body, a narrow and faint penumbra was ſeen on the outſide of the dark ſhadow. And on the outſide of this there was a tract more ſtrongly illuminated than the reſt of the paper.

The breadth of the external penumbra increaſed with the diſtance of the ſhadow from the cylinder, and the breadth of the tract of light on the outſide of it was alſo enlarged; but its ſplendor diminiſhed with the diſtance.

He repeated theſe experiments with three other cylinders of different dimenſions; and from them all he inferred, that every opaque cylindrical body, expoſed to the light of the ſun, makes a ſhadow which is black and dark to the diſtance of 38 to 45 diameters of the cylinder which forms it; and that, at a greater diſtance, the middle part begins to be illuminated in the manner deſcribed above.

In explaining theſe appearances, our author ſuppoſes that the light which diluted the middle part of the ſhadow was occaſioned by the inflection of the rays, which, bending inwards on their near approach to the body, did at a certain diſtance enlighten all the ſhadow, except the edges, which was left undiſturbed. At the ſame time other rays were deflected from the body, and formed a ſtrong light on the outſide of the ſhadow, and which might at the ſame time contribute to dilute the outer ſhadow, though he ſuppoſed that penumbra to be occaſioned principally by that part of the paper not being enlightened, except by a part of the ſun's diſk only, according to the known principles of optics.

54 Concerning thoſe of globes. The ſame experiments he made with globes of ſeveral diameters; but he found, that, whereas the ſhadows of the cylinders did not diſappear but at the diſtance of 41 of their diameters, thoſe of the globes were not viſible beyond 15 of their diameters; which he thought was owing to the light being inflected on every ſide of a globe, and conſequently in ſuch a quantity as to diſperſe the ſhadows ſooner than in the caſe of the cylinders.

In all theſe caſes the penumbra occaſioned by the inflected light, began to be viſible at a leſs diſtance from the body in the ſtronger light of the ſun than in a weaker, on account of the greater quantity of rays inflected in thoſe circumſtances.

55 His miſtake concerning the moon. Conſidering the analogy between theſe experiments and the phenomena of an eclipſe of the moon, immerſed in the ſhadow of the earth, he imagined, that part of the light by which ſhe is then viſible is inflected light, and not that which is refracted by the atmoſphere; though this may be ſo copious as to efface ſeveral of the above-mentioned appearances, occaſioned by inflected light only. But this gentleman ſhould have conſidered, that as no light is inflected but what paſſes exceedingly near to any body, perhaps ſo near as the diſtance of $\frac{1}{20}$ part of an inch, this cauſe muſt be altogether inadequate to the effect.

Being ſenſible that the above-mentioned phenomena of the ſhadows were cauſed by inflected light, he was induced to give more particular attention to this remarkable property; and in order to it to repeat the experiments of Grimaldi and Sir Iſaac Newton in a darkened room. In doing this, he preſently obſerved, that, beſides the enlarged ſhadow of a hair, a fine needle, &c. the bright gleam of light that bordered it, and the three coloured rings next to this enlightened part, when the ſhadow was at a conſiderable diſtance from the hair, the dark central ſhadow was divided in the middle by a mixture of light; and that it was not of the ſame denſity, except when it was very near the hair.

This new appearance will be seen to be exactly ſimilar to what our philoſopher had obſerved with reſpect to the ſhadows in the open day-light above-mentioned; but the following obſervations, which he made with ſome variation of his apparatus, are much more curious and ſtriking, though they ariſe from the ſame cauſe.

Having placed a briſtle, which is thicker than a common hair, in the rays of the ſun, admitted into a dark chamber by a ſmall hole, at the diſtance of nine feet from the hole, it made a ſhadow, which, being received at five or ſix feet from the object, he obſerved to conſiſt of ſeveral ſtreaks of light and ſhade. The middle part was a faint ſhadow, or rather a kind of penumbra, bordered by a darker ſhadow, and after that by a narrower penumbra, next to which was a light ſtreak broader than the dark part, and next to the ſtreak of light the red, violet, and blue colours were ſeen as in the ſhadow of the hair.

In the ſame manner he placed, in the ſame rays of the ſun, ſeveral needles of different ſizes; but the appearances were ſo exceedingly various, tho' ſufficiently ſingular, that he does not recite them particularly, but chooſes rather to give, at ſome length, the obſervations he made on the ſhadows of two plates, as by that means he could better explain the phenomena of the round bodies.

56 Experiments concerning the ſhadows of metalline plates.

He expoſed in the rays of the ſun, admitted by a ſmall hole into a dark chamber, a plate that was two inches long, and a little more than half a line broad. This plate being fixed perpendicularly to the rays, at the diſtance of nine feet from the hole, a faint light was ſeen uniformly diſperſed over the ſhadow, when it was received perpendicularly to it, and very near. The ſhadow of the ſame plate being received at the diſtance of two feet and a half, was divided into four very narrow black ſtreaks, ſeparated by ſmall lighter intervals equal to them. The boundaries of this ſhadow on each ſide had a penumbra, which was terminated by a very ſtrong light, next to which were the coloured ſtreaks of red, violet, and blue, as before. This is repreſented in Plate CCVII. fig. 4.

The ſhadow of the ſame plate at $4\frac{1}{2}$ feet diſtance from it, was divided into two black ſtreaks only, the two outermoſt having diſappeared, as in fig. 5.; but theſe two black ſtreaks which remained were broader than before, and ſeparated by a lighter ſhade, twice as broad as one of the former black ſtreaks, when the ſhadow was taken at $2\frac{1}{2}$ feet. This penumbra in the middle had a tinge of red. After the two black ſtreaks there appeared a pretty ſtrong penumbra, terminated by the two ſtreaks of light, which were now broad and ſplendid, after which followed the coloured ſtreaks.

A ſecond plate, two inches long and a line broad, being placed like the former, 14 feet from the hole by which the rays of the ſun were admitted, its ſhadow being received perpendicularly very near the plate, was illuminated by a faint light, equally diſperſed, as in the the caſe of the preceding plate. But being received at the diſtance of 13 feet from the plate, ſix ſmall black ſtreaks began to be viſible, as in fig. 6. At 17 feet from the plate, the black ſtreaks were broader, more diſtinct, and more ſeparated from the ſtreaks that were leſs dark. At 42 feet from the plate, only two black ſtreaks were ſeen in the middle of the penumbra, as in fig. 7. This middle penumbra between the two black ſtreaks was tinged with red. Next to the black ſtreaks there always appeared the ſtreaks of light, which were broad, and the coloured ſtreaks next to them.

Receiving the ſhadow of the ſame plate at the diſtance of 72 feet, the appearances were the ſame as in the former ſituation, except that the two black ſtreaks were broader, and the interval between them, occupied by the penumbra, was broader alſo, and tinged with a deeper red.

In the ſame rays of the ſun he placed different plates, and larger than the former, one of them a line and a half, another two lines, another three lines broad, &c. but receiving their ſhadows upon paper, he could not perceive in them thoſe ſtreaks of faint light which he had obſerved in the ſhadows of the ſmall plates, though he received theſe ſhadows at the diſtance of 56 feet. Nothing was ſeen but a weak light, equally diffuſed, as in the ſhadows of the two ſmalleſt plates, received very near them. But had his dark chamber been large enough, he did not doubt, but that, at a proper diſtance, there would have been the ſame appearances in the ſhadows of the larger plates as in thoſe of the ſmalleſt. For the ſame reaſon, he ſuppoſed, that, if the ſhadows of the ſmall needles could have been diſtinctly viewed very near thoſe bodies, the different ſtreaks of light and ſhade would have been as viſible in them as in thoſe of the ſmall plates; and indeed he did obſerve the ſame appearances in the ſhadows of needles of a middling ſize.

The ſtreaks of light in theſe ſhadows our author aſcribed to the rays of light which are inflected at different diſtances from the bodies; and he imagined that their croſſing one another was ſufficient to account for the variations obſervable in them at different diſtances.

The extraordinary ſize of the ſhadows of theſe ſmall ſubſtances M. Maraldi thought to be occaſioned by the ſhadow from the enlightened part of the ſky, added to that which was made by the light of the ſun, and alſo to a vortex occaſioned by the circulation of the inflected light behind the object; but our readers will probably not think it neceſſary for us either to produce all his reaſons for this hypotheſis, or to enter into a refutation of them.

Our author having made the preceding experiments upon ſingle long ſubſtances, had the curioſity to place two of them ſo as to croſs one another in a beam of the ſun's light. The ſhadows of two hairs placed in this manner, and received at ſome diſtance from them, appeared to be painted reciprocally one upon the other, ſo that the obſcure part of one of them was viſible upon the obſcure part of the other. The ſtreaks of light alſo croſſed one another, and the coloured ſtreaks did the ſame.

Having placed a needle and a hair croſſing one another, their ſhadows, at the ſame diſtance, exhibited the ſame appearances as the ſhadows of the two hairs, though the ſhadow of the needle was the ſtronger.

He alſo placed in the rays of the ſun a briſtle and a plate of iron a line thick, ſo that they croſſed one another

another obliquely; and when their ſhadows were received at the ſame diſtance, the light and dark ſtreaks of the ſhadow of the briſtle were viſible ſo far as the middle of the ſhadow of the plate on the ſide of the acute angle, but not on the ſide of the obtuſe angle, whether the briſtle or the plate were placed next to the rays. The plate made a ſhadow ſufficiently dark, divided into ſix black ſtreaks; and theſe were again divided by as many light ones equal to them; and yet all the ſtreaks belonging to the ſhadow of the briſtles were viſible upon it, as in fig. 8. To explain this appearance, he ſuppoſed that the rays of the ſun glid a little along the briſtle, ſo as to enlighten part of that which is behind the plate. But this ſeems to be an arbitrary and improbable ſuppoſition.

Our philoſopher did not fail to expoſe ſeveral ſmall globes in the light of the ſun in his dark chamber, and to compare their ſhadows with thoſe of the long ſubſtances, as he had done in the day-light, and the appearances were ſtill ſimilar. It was particularly evident, that there was much more light in the ſhadows of the globes than in thoſe of the cylinders, not only when they were both of an equal diameter, but when that of the globe was larger than that of the cylinder, and the ſhadows of both the bodies were received at the ſame diſtance. He alſo obſerved, that he could perceive no difference of light in the ſhadows of the plates which were a little more than one line broad, though they were received at the diſtance of 72 feet; but he could eaſily ſee a difference of ſhades in thoſe of the globes, taken at the ſame diſtance, tho' they were $2\frac{1}{4}$ lines in diameter.

In order to explain the colours at the edges of theſe ſhadows, he contrived to throw ſome of the ſhadows upon others; and the following obſervations, though they did not enable him to accompliſh what he intended, are curious and worth reciting.

57 Experiments with a mixture of coloured ſhadows.

Having thrown ſeveral of the ſimilar colours upon one another, and thereby produced a tinge more lively than before, he threw the gleam of light, which always intervened between the colours and the darker part of the ſhadow, upon different parts of other ſhadows; and obſerved, that, when it fell upon the exterior penumbra made by another needle, it produced a beautiful ſky-blue colour, almoſt like that which was produced by two blue colours thrown together. When the ſame gleam of light fell upon the deeper ſhadow in the middle, it produced a red colour; which ſeemed to prove, that the reddiſh colour in the middle of ſeveral of the ſhadows might come from the little light inflected into that place. But here our author ſeems to have been miſled by ſome falſe hypotheſis concerning colours.

He placed two plates of iron, each three or four lines broad, very near one another, but with a very ſmall interval between them; and having placed them in the rays of the ſun, and received their ſhadows at the diſtance of 15 or 20 feet from them, he ſaw no light between them but a continued ſhadow, in the middle of which were ſome ſtreaks of a lively purple, parallel to one another, and ſeparated by other black ſtreaks; but between them there were other ſtreaks, both of a very faint green, and alſo of a pale yellow. He alſo informs us, that M. Deliſle had obſerved colours in the ſtreaks of light and ſhade, which are obſervable in ſhadows taken near the bodies.

58 M. Mairan's obſervations.

Among thoſe who followed Sir Iſaac Newton in his obſervations on the inflection of light, we alſo find the ingenious M. Mairan: but, without attempting the diſcovery of new facts, he only endeavoured to explain the old ones, by the hypotheſis of an atmoſphere ſurrounding all bodies; and conſequently making two reflections and refractions of the light that impinges upon them, one at the ſurface of the atmoſphere, and the other at that of the body itſelf. This atmoſphere he ſuppoſed to be of a variable denſity and refractive power, like the air.

59 Diſcoveries of M. Du Tour.

M. Mairan was ſucceeded by M. Du Tour, who thought the variable atmoſphere ſuperfluous, and imagined that he could account for all the phenomena by the help of an atmoſphere of an uniform denſity, and of a leſs refractive power than the air ſurrounding all bodies. But what we are moſt obliged to this gentleman for is, not his ingenious *hypotheſis*, but the beautiful variety with which he has exhibited the *experiments*, which will render it much eaſier for any perſon to inveſtigate the true cauſes of them.

Before M. Du Tour gave his attention to this ſubject, only three fringes had been obſerved in the colours produced by the inflection of light; but he was accidentally led to obſerve a greater number of them, and hit upon the following ingenious method of making them all appear very diſtinct.

Plate CCVII.

He took a circular board ABED (fig. 9.), 13 inches in diameter, the ſurface of which was black, except at the edge, where there was a ring of white paper about three lines broad, in order to trace the circumference of a circle, divided into 360 degrees, beginning at the point A, and reckoning 180 degrees on each hand to the point E; B and D being each of them placed at 90 degrees. A ſlip of parchment three inches broad, and diſpoſed in the form of a hoop, was faſtened round the board, and pierced at the point E with a ſquare hole, each ſide being four or five lines, in order to introduce a ray of the ſun's light. Laſtly, in the centre of the board C, and perpendicular to it, he fixed a pin about $\frac{1}{3}$ of a line in diameter.

This hoop being ſo diſpoſed, that a ray of light entering the dark chamber, through a vertical cleft of two lines and a half in length, and about as wide as the diameter of the pin, went through the hole at E, and paſſing parallel to the plane of the board, projected the image of the ſun and the ſhadow of the pin at A. In theſe circumſtances he obſerved,

1. That quite round the concave ſurface of this hoop, there were a multitude of coloured ſtreaks; but that the ſpace *m* A *n*, of about 18 degrees, the middle of which was occupied by the image of the ſun, was covered with a faint light only.

2. The order of the colours in theſe ſtreaks was generally ſuch that the moſt refrangible rays were the neareſt to the incident ray ECA; ſo that, beginning from the point A, the violet was the firſt, and the red the laſt colour in each of the ſtreaks. In ſome of them, however, the colours were diſpoſed in a contrary order.

3. The image of the ſun, projected on each ſide of the point A, was divided by the ſhadow of the pin, which was bordered by two luminous ſtreaks.

4. The coloured ſtreaks were narrower in ſome parts of the hoop than others, and generally decreaſed in breadth in receding from the point A.

5. Among theſe coloured ſtreaks, there were ſometimes others which were white, a line or a line and an half in breadth, which were always bordered on both ſides by a ſtreak of orange colour, at leaſt when the light of the ſun was intenſe, and the chamber ſufficiently dark.

From this experiment he thought it was evident, that the rays which paſſed beyond the pin were not the only ones that were decompoſed, for that thoſe which are reflected back from the pin were decompoſed alſo; from which he concluded, that they muſt have undergone ſome refraction. He alſo thought that thoſe which went beyond the pin ſuffered a reflection, ſo that they were all affected in a ſimilar manner.

In order to account for theſe facts, our author deſcribes the progreſs of a ray of light through an uniform atmoſphere, which he ſuppoſes to ſurround the pin; and ſhews, that the differently refrangible rays will be ſeparated at their emergence from it: but he refers to ſome experiments and obſervations in a future memoir, to demonſtrate that all the coloured ſtreaks are produced by rays that are both reflected and refracted.

Plate CCVII. 60 Account of Du Tour's hypotheſis.

To give ſome idea of his hypotheſis, he ſhews that the ray *a b*, fig. 10. after being refracted at *b*, reflected at *r* and *u*, and again refracted at *s* and *t*, will be divided into its proper colours; the leaſt refrangible or the red rays iſſuing at *x*, and the moſt refrangible or violet at *y*; which agrees with his obſervations. Thoſe ſtreaks in which the colours appear in a contrary order he thinks are to be aſcribed to inequalities in the ſurface of the pin. This might eaſily have been aſcertained by turning the pin round, in which caſe theſe differently-coloured ſtreaks would have changed their places.

If any perſon ſhould chooſe to repeat theſe experiments, he obſerves that it requires that the ſky be very clear and free from vapours, in order to exhibit the colours with the greateſt diſtinctneſs; ſince even the vapours that are imperceptible, will diminiſh the luſtre of the colours on every part of the hoop, and even efface ſome of them, eſpecially thoſe which are on that in which the beam of light enters, as at E, where the colours are always fainter than in any other place, and indeed can never be diſtinguiſhed except when the hole E is confined by black ſubſtances, ſo as to intercept a part of the light that might reach the pin; and unleſs alſo thoſe rays which go beyond the pin to form the image of the ſun at A be ſtopped, ſo that no rays are viſible except thoſe that are reflected towards the hole, and which make the faint ſtreaks.

The coloured ſtreaks that are next the ſhadow of the pin, he ſhews, are formed by thoſe rays which, entering the atmoſphere, do not fall upon the pin; and, without any reflection, are only refracted at their entering and leaving the atmoſphere, as at *b* and *r u*, fig. 11. In this caſe, the red or leaſt refrangible rays will iſſue at *r*, and the violet at *u*.

To diſtinguiſh the rays which fell upon the hoop in any particular direction, from thoſe that came in any other, he made an opening in the hoop, as at P, by which means he could, with advantage, and at any diſtance from the centre, obſerve thoſe rays unmixed with any other.

To account for the coloured ſtreaks being larger next the ſhadow of the pin, and growing narrower to the place where the light was admitted, he ſhews, by fig. 12. that the rays *a b* are farther ſeparated by both the refractions than the rays *c d*.

Sometimes our author obſerved, that the broader ſtreaks were not diſpoſed in this regular order; but then he found, that, by turning the pin, they changed their places, ſo that this circumſtance muſt have been an irregularity depending upon the accidental ſurface of the pin.

The white ſtreaks intermixed with the coloured ones he aſcribes to ſmall cavities in the ſurface of the pin, or ſome other foreign circumſtance; for they alſo changed their places when the pin was made to turn upon its axis.

Other obſervations of our author ſeem to prove that the refracting atmoſpheres ſurrounding all kinds of bodies are of the ſame ſize; for when he placed a great variety of ſubſtances, and of different ſizes alſo, he always found the coloured ſtreaks of the ſame dimenſions.

M. Du Tour obſerves that his hypotheſis contradicts an obſervation of Sir Iſaac Newton, that thoſe rays which paſs the neareſt to any body are the moſt inflected; but he thinks that Newton's obſervations were not ſufficiently accurate. Beſides, he obſerves, that Newton only ſaid that *he thought it to be ſo*, without aſſerting it poſitively.

Since the rays which formed theſe coloured ſtreaks are but little diverted out of their way, our author infers that this atmoſphere is of ſmall extent, and that its refractive power is not much leſs than that of air.

Expoſing two pieces of paper in the beam of light, ſo that part of it paſſed between two planes formed by them, M. Du Tour obſerved, that the edges of this light, received upon paper, were bordered with two orange-coloured ſtreaks, which Newton had not taken notice of in any of his experiments. To account for them, he ſuppoſes, that in fig. 13. the more refrangible of the rays which enter at *b* are ſo refracted, that they do not reach the ſurface of the body itſelf at R; ſo that the red and orange-coloured light may be reflected from thence in the direction *d* M, where the orange-coloured ſtreaks will be formed; and, for the ſame reaſon, another ſtreak of orange will be formed at *m*, by the rays which enter the atmoſphere on the other ſide of the chink. In a ſimilar manner he accounts for the orange-coloured fringes at the borders of the white ſtreaks, in the experiment of the hoop.

The blue rays, which are not reflected at R, he ſuppoſes paſs on to I, and that of theſe rays the blue tinge obſervable in the ſhadows of ſome bodies are formed.

61 Objects ſometimes magnified by the inflection of light.

M. Le Cat has well explained a phenomenon of viſion depending upon the inflection of light, which ſhews, that, in ſome caſes, objects appear magnified by this means. Looking at a diſtant ſteeple, when a wire, of a leſs diameter than the pupil of his eye, was held pretty near to it, and drawing it ſeveral times betwixt

betwixt his eye and that object, he was furprifed to find, that, every time the wire paffed before his pupil, the fteeple feemed to change its place, and fome hills beyond the fteeple feemed to have the fame motion, juft as if a lens had been drawn betwixt his eye and them.

Examining this appearance more attentively, he found that there was a pofition of the wire, but very difficult to keep, in which the fteeple feemed not to have any motion, when the wire was paffed before his eye; and in this cafe the fteeple appeared lefs diftinctly, and feemed to be magnified. Thefe effects being fimilar to thofe of a lens, he attended to them more particularly; and placed his eye in fuch a manner, with refpect to the fteeple, that the rays of light by which he faw it muft come very clofe to the edge of a window, where he had placed himfelf to make his obfervations. Then paffing the wire once more before his eye, he obferved, that, when it was in the vifual axis, the fteeple appeared nearer to the window, on whichever fide the wire was made to approach. He repeated this experiment, and conftantly with the fame refult, the object being always magnified, and nearly doubled, by this means.

This phenomenon is eafily explained by fig. 14. in which B reprefents the eye, A the fteeple, and C the diameter of the wire. The black lines exprefs the cone of light by which the natural image of the fteeple A is formed, and which is much narrower than the diameter of the wire C; but the dotted lines include not only that cone of light, ftopped and turned out of its courfe by the wire, but alfo more diftant rays inflected by the wire, and thereby thrown more converging into the pupil; juft as would have been the effect of the interpofition of a lens between the eye and the object. The refult of this experiment was the fame, whatever fubftances he made ufe of in the place of the wire, provided they were of the fame diameter.

62 Mifcellaneous obfervations.

This difcovery, depending upon the inflection of the rays of light, led him to feveral others depending upon the fame principle. Thus he magnified fmall objects, as the head of a pin, by looking at them through a fmall hole in a card; fo that the rays which formed the image muft neceffarily pafs fo near the circumference of the hole, as to be attracted by it. He alfo obferved, that, by bringing his finger near the cone of light, which tranfmitted to him the image of any object well infulated, as a red coal in the midft of cinders, or a black coal in the midft of the fire, the object feemed to ftretch itfelf towards his finger, as it approached, and to follow it to a certain diftance when it was withdrawn. He thought it was owing to the fame caufe, that the clouds which pafs over the face of the fun occafion various motions in the fhadow of bodies; and when thefe clouds are interrupted in different places, thofe fhadows feems to dance, which is particularly vifible in the fhadows made by the leads in glafs-windows. It was to the fame inflection of light that he afcribed, in part, the prifmatic colours which he faw by the means of a very fine pin, placed near to his eye, and on which he made the light of a candle to fall obliquely.

§ 5. *Difcoveries concerning Vifion.*

Maurolycus was the firft who fhewed the true theory of vifion, by demonftrating that the cryftalline humour of the eye is a lens which collects the light iffuing from external objects, and throws them upon the retina, where is the focus of each pencil. He did not, however, find out, that, by means of this refraction of the rays, an image of every vifible object was formed upon the retina, though this feems hardly to have been a ftep beyond the difcovery he had already made. Montucla conjectures, that he was prevented from coming to this difficulty of accounting for the upright appearance of objects, as this image is always inverted. This difcovery was made by Kepler; but he, too, was much difficulted with the inverted pofition of the image. The rectification of thefe images, he fays, is the bufinefs of the mind; which, when it perceives an impreffion on the lower part of the retina, confiders it as made by rays proceeding from the higher parts of objects; tracing the rays back to the pupil, where they crofs one another. But this hypothefis can fcarcely be deemed fatisfactory.—Kepler did not pretend to account for the manner in which the mind perceives the images upon the retina, and very much blames Vitellio for attempting prematurely to determine a queftion of this nature, and which indeed, he fays, does not belong to optics. He accounts, however, though not in a fatisfactory manner, for the power we have of feeing diftinctly at different diftances.

63 Difcoveries of Maurolycus, Kepler, &c. concerning vifion.

64 Difcoveries of Scheiner.

The difcovery concerning vifion was completed by Scheiner. For, in cutting away the coats of the back part of the eyes of fheep and oxen, and prefenting feveral objects before them, within the ufual diftance of vifion, he faw their images diftinctly and beautifully painted upon the retina. He did the fame thing with the human eye, and exhibited this curious experiment at Rome in 1625. He takes particular notice of the refemblance between the eye and the camera obfcura, and explains a variety of methods to make the images of objects erect. As to the images of objects being inverted in the eye, he acquiefces in the reafon given for it by Kepler. He knew that the pupil of the eye is enlarged in order to view remote objects, and that it is contracted while we are viewing thofe that are near; and this he proved by experiment, and illuftrated by figures.

Scheiner alfo took a good deal of pains to afcertain the denfity and refractive power of all the humours of the eye by comparing their magnifying power with that of water or glafs in the fame form and circumftances. The refult of his inquiries was, that the aqueous humour doth not differ much from water in this refpect, nor the cryftalline from glafs; and that the vitreous humour is a medium between both. He alfo very accurately and minutely traces the progrefs of the rays of light through all the humours of the eye, and after difcuffing every poffible hypothefis concerning the proper feat of vifion, he demonftrates that it is in the retina, and fhews that this was the opinion of Alhazen, Vitellio, Kepler, and all the moft eminent philofophers. He produces many reafons of his own for this hypothefis; anfwers a great number of objections to it; and, by a variety of arguments, refutes the opinion of former times, that the feat of vifion is in the cryftalline.

Defcartes makes a good number of obfervations on the

65 Discoveries of Descartes.

the phenomena of vision. He explains satisfactorily the natural methods of judging of the magnitudes, situations and distances, of objects by the direction of the optic axes; comparing it to a blind man's judging of the size and distance of an object, by feeling at it with two sticks of a known length, when the hands in which he holds them are at a known distance from each other. He also observes, that having been accustomed to judge of the situation of objects by their images falling on a particular part of the eye; if by any distortion of the eye they fall on a different place, we are apt to mistake their situation, or imagine one object to be two; as, till we become accustomed to it, we imagine one stick to be two, when it is placed between two contiguous fingers laid across one another. But he observes, that all the methods we have of judging of the distances of objects are very uncertain, and extend but to narrow limits. The direction of the optic axes, he says, will not serve us beyond 15 or 20 feet, and the change of form of the crystalline not more than three or four feet. For he imagined that the eye conforms itself to the view of near or distant objects by a change in the curvature of the crystalline, which he supposed to be a muscle, the tendons of it being the processus ciliares. In another place, he says, that the change in the conformation of the eye is of no use to us for the purpose of judging of distances beyond four or five feet, and the angle of the optic axes not more than 100 or 200 feet. For this reason, he says, that the sun and moon are conceived to be much more nearly of the same size than they are in reality. White and luminous objects, he says, appear larger than others, and also the parts contiguous to those on which the rays actually impinge; and for the same reason, if the objects be small, and placed at a great distance, they will always appear round, the figure of the angles disappearing. The description of the eye itself, the various modes of vision and optical deceptions to which we are liable, belong properly to the succeeding part of this treatise.

§ 6. *Of Optical Instruments, and Discoveries concerning them.*

66 Invention of spectacles.

So little were the ancients acquainted with the science of Optics, that they seem to have have had no instruments of the optical kind, excepting the glass globes and speculums formerly mentioned, which they used in some cases for magnifying and burning. Alhazen, as we have seen, gave the first hint of the invention of spectacles, and it is probable that they were found out soon after his time. From the writings of Alhazen and the observations and experiments of Bacon together, it is not improbable that some monks gradually hit upon the construction of spectacles; to which Bacon's lesser segment, notwithstanding his mistake concerning it, was a nearer approach than Alhazen's larger one. Whoever they were that pursued the discoveries of Bacon, they probably observed, that a very small convex glass, when held at a greater distance from the book, would magnify the letters more than when it was placed close to them, in which position only Bacon seems to have used it. In the next place, they might try whether two of these small segments of a sphere placed together, or a glass convex on both sides, would not magnify more than one of them. They would then find, that two of these glasses, one for each eye, would answer the purpose of reading better than one; and lastly they might find, that different degrees of convexity suited different persons.

It is certain that spectacles were well known in the 13th century, and not long before. It is said that Alexander Spina, a native of Pisa, who died in 1313, and who was very ingenious in executing whatever he saw or heard of as having been done by others, happened to see a pair of spectacles in the hands of a person who would not explain them to him; but that he succeeded in making a pair for himself, and immediately made the construction public, for the good of others. It is also inscribed on the tomb of Salvinus Armatus, a nobleman of Florence, who died 1317, that he was the inventor of spectacles.

67 Of concave glasses.

The use of concave glasses, to help those persons who are short-sighted, was, probably, a discovery that did not follow long after that of convex ones, for the relief of those whose sight is defective in the contrary extreme, though we find no trace of this improvement. Whoever made this discovery, it was probably the result of nothing more than a random experiment. Perhaps a person who was short-sighted, finding that convex glasses did him more harm than good, had the curiosity to make trial of a contrary curvature of the glass.

68 Descartes's account of the invention of telescopes.

From this time, though both convex and concave lenses were sufficiently common, yet no attempt was made to form a telescope by a combination of them, till the end of the 16th century. Descartes considers James Metius, a person who was no mathematician, though his father and brother had applied to those sciences, as the first constructor of a telescope; and says, that as he was amusing himself with making mirrors and burning-glasses, he casually thought of looking thro' two of his lenses at a time; and that happening to take one that was convex and another that was concave, and happening also to hit upon a pretty good adjustment of them, he found, that, by looking thro' them, distant objects appeared very large and distinct. In fact, without knowing it, he had made a telescope.

69 Other accounts.

Other persons say, that this great discovery was first made by John Lippersheim, a maker of spectacles at Middleburgh, or rather by his children; who, like, Metius, were diverting themselves with looking thro' two glasses at a time, and placing them at different distances from one another. But Borellus, the author of a book intitled, *De vero telescopii inventore*, gives this honour to Zacharias Joannides, i. e. Jansen, another maker of spectacles at the same place, who made the first telescope in 1590; and it seems now to be the general opinion, that this account of Borellus is the most probable.

70 Borellus's account probably the true one.

Indeed, Borellus's account of the discovery of telescopes is so circumstantial, and so well authenticated, that it does not seem possible to call it in question. It is not true, he says, that this great discovery was made by a person who was no philosopher: for Zacharias Jansen was a diligent inquirer into nature; and being engaged in these pursuits, he was trying what uses could be made of lenses for those purposes, when he

he fortunately hit upon the conſtruction.

This ingenious mechanic, or rather philoſopher, had no ſooner found the arrangement of glaſſes that produced the effect he deſired, than he incloſed them in a tube, and ran with his inſtrument to prince Maurice; who immediately conceiving that it might be of uſe to him in his wars, deſired the author to keep it a ſecret. But this, though attempted for ſome time, was found to be impoſſible; and ſeveral perſons in that city immediately applied themſelves to the making and ſelling of teleſcopes. One of the moſt diſtinguiſhed of theſe was Hans Laprey, called *Lipperſheim* by Sirturus. By him ſome perſon in Holland being very early ſupplied with a teleſcope, he paſſed with many for the inventor; but both Metius above-mentioned, and Cornelius Drebell of Alcmar, in Holland, applied to the inventor himſelf in 1620; as alſo did Galileo, and many others. The firſt teleſcope made by Janſen did not exceed 15 or 16 inches in length; but Sirturus, who ſays that he had ſeen it, and made uſe of it, thought it the beſt that he had ever examined.

71 The firſt teleſcope an exceedingly good one.

Janſen, having a philoſophical turn, preſently applied his inſtrument to ſuch purpoſes as he had in view when he hit upon the conſtruction. Directing it towards celeſtial objects, he diſtinctly viewed the ſpots on the ſurface of the moon; and diſcovered many new ſtars, particularly ſeven pretty conſiderable ones in the great bear. His ſon Joannes Zachariæ, noted the lucid circle near the limb of the moon, from whence ſeveral bright rays ſeem to dart in different directions; and he ſays, that the full moon viewed through this inſtrument, did not appear flat, but was evidently ſpherical, the middle part being prominent. Jupiter alſo, he ſays, appeared round, and rather ſpherical; and ſometimes he perceived two, ſometimes three, and at the moſt four ſmall ſtars, a little above or below him; and as far as he could obſerve, they performed revolutions round him; but this, he ſays, he leaves to the conſideration of aſtronomers. This, it is probable, was the firſt obſervation of the ſatellites of Jupiter, tho' the perſon who made it was not aware of the importance of his diſcovery.

72 Honour of the invention claimed by Fontana.

One Francis Fontana, an Italian, alſo claims the invention; but as he did not pretend to have made it before the year 1608, and as it is well known that the inſtruments were made and ſold in Holland ſome time before, his pretenſions to a ſecond diſcovery are not much regarded.

73 A teleſcope made by Galileo without ſeeing one.

There are ſome, who ſay that Galileo was the inventor of teleſcopes; but he himſelf acknowledges, that he firſt heard of the inſtrument from a German; but he ſays, that being informed of nothing more than the effects of it, firſt by common report, and a few days after by a French nobleman, J. Badovere, at Paris, he himſelf diſcovered the conſtruction, by conſidering the nature of refraction: and thus he had much more real merit than the inventor himſelf.

The account of what Galileo actually did in this buſineſs, is ſo circumſtantially related by the author of his life, prefixed to the quarto edition of his works, printed at Venice in 1744, and it contains ſo many particulars, which cannot but be pleaſing to every perſon who is intereſted in the hiſtory of teleſcopes, that we ſhall abridge a part of it, intermixing circumſtances collected from other accounts.

74 Account of his diſcoveries.

About April or May, in 1609, it was reported at Venice, where Galileo (who was profeſſor of mathematics in the univerſity of Padua) then happened to be, that a Dutchman had preſented to Count Maurice of Naſſau, a certain optical inſtrument, by means of which, diſtant objects appeared as if they were near; but no farther account of the diſcovery had reached that place, tho' this was near 20 years after the firſt diſcovery. Struck, however, with this account, Galileo inſtantly returned to Padua, conſidering what kind of an inſtrument this muſt be. The night following, the conſtruction occurred to him; and the day after, putting the parts of the inſtrument together, as he had previouſly conceived of it, and, notwithſtanding the imperfection of the glaſſes that he could then procure, the effect anſwered his expectations, as he preſently acquainted his friends at Venice; to which place, he ſix days afterwards carried another and a better inſtrument that he had made, and where, from ſeveral eminences, he ſhewed to ſome of the principal ſenators of that republic a variety of diſtant objects, to their very great aſtoniſhment. When he had made farther improvements in the inſtrument, he, with his uſual generoſity and frankneſs in communicating his diſcoveries, made a preſent of one of them to the Doge, Leonardo Donati, and at the ſame time to all the ſenate of Venice; giving along with the inſtrument, a written paper, in which he explained the ſtructure and wonderful uſes that might be made of it both by land and at ſea. In return for ſo noble an entertainment, the republic, on the 25th of Auguſt, in the ſame year, more than tripled his ſalary as profeſſor.

Our philoſopher, having amuſed himſelf for ſome time with the view of terreſtrial objects, at length directed his tube towards the heavens; and, obſerving the moon, he found, that the ſurface of it was diverſified with hills and valleys, like the earth. He found that the *via lactea* and *nebulæ* conſiſted of a collection of fixed ſtars, which, on account either of their vaſt diſtance, or extreme ſmallneſs, were inviſible to the naked eye. He alſo diſcovered innumerable fixed ſtars diſperſed over the face of the heavens, which had been unknown to all the ancients; and examining Jupiter, with a better inſtrument than any he had made before, he found that he was accompanied by four ſtars, which, in certain fixed periods, performed revolutions round him, and which, in honour of the houſe of Medici, he called *Medicean planets*.

This diſcovery he made in January 1610, new ſtyle; and continuing his obſervations the whole of February following, in the beginning of March next he publiſhed an account of all his diſcoveries, in his *Nuncius Sidereus*, printed at Venice, and dedicated to Coſimo, great duke of Tuſcany, who, by a letter which he wrote to him on the 10th of July 1610, invited him to quit Padua, and aſſigned him an ample ſtipend, as primate and extraordinary profeſſor at Piſa, but without any obligation to read lectures, or to reſide.

The extraordinary diſcoveries contained in the Nuncius Sidereus, which was immediately reprinted both in Germany and France, was the cauſe of much ſpeculation and debate among the philoſophers and aſtronomer's of that time; many of whom could not be brought

brought to give any credit to Galileo's account, while others endeavoured to decry his discoveries as being nothing more than fictions or illusions. Some could not be prevailed upon even to look through a telescope; so devoted were they to the system of Aristotle, and so averse to admit any other source of knowledge besides his writings. When it was found to be in vain to oppose the evidence of sense, some did not scruple to assert that the invention was taken from Aristotle; and producing a passage from his writings, in which he attempts to give a reason why stars are seen in the day-time from the bottom of a deep well, said, that the well corresponded to the tube of the telescope, and that the vapours which arose from it gave the hint of putting glasses into it; and lastly, that in both cases the sight is strengthened by the transmission of the rays through a thick and dark medium. Galileo himself tells this story with a great deal of humour; comparing such men to alchymists, who imagine that the art of making gold was known to the ancients, but lay concealed under the fables of the poets.

In the beginning of July of the same year, 1610, Galileo being still at Padua, and getting an imperfect view of Saturn's ring, imagined that that planet consisted of three parts; and therefore, in the account which he gave of this discovery to his friends, he calls it *planetam tergeminum*.

Whilst he was still at Padua, which must have been either in the same month of July, or the beginning of August following, he observed some spots on the face of the sun: but, contrary to his usual custom, he did not choose, at that time, to publish his discovery; partly for fear of incurring more of the hatred of many obstinate peripatetics; and partly, in order to make more exact observations on this remarkable phenomenon, and to form some conjecture concerning the probable cause of it. He therefore contented himself with communicating his observations to some of his friends at Padua and Venice, among whom we find the name of father Paul. This delay, however, was the cause of this discovery being contested with him by the famous Scheiner, who likewise made the same observation in Oct. 1611, and we suppose had anticipated Galileo in the publication of it.

About the end of August, Galileo left Padua and went to Florence; and in November following he was satisfied, that, from the September preceding, Venus had been continually increasing in bulk, and that she changed her phases like the moon. About the end of March 1611, Galileo went to Rome, where he gratified the cardinals, and all the principal nobility, with a view of the new wonders he had discovered in the heavens, and among others the solar spots.

75 Named *Lynceus* from them.

From these discoveries Galileo obtained the name of *Lynceus*, who was famous in antiquity for the acuteness of his sight; and moreover, the marquis of Monticelli instituted an academy, with the title of *De' Lincei*, and made him a member of it. Twenty-nine years Galileo enjoyed the use of his telescope, continually enriching astronomy with his observations: but by too close an application to that instrument, and the detriment he received from the nocturnal air, his eyes grew gradually weaker, till in 1639 he became totally blind; a calamity which, however, neither broke his spirits, nor interrupted the course of his studies.

The first telescope that Galileo constructed magnified only three times: but presently after, he made another which magnified 18 times: and afterwards, with great trouble and expence, he constructed one that magnified 33 times; and with this it was that he discovered the satellites of Jupiter, and the spots of the sun. 76 Account of his telescopes.

Notwithstanding Galileo must be allowed to have considerable merit with respect to telescopes, it was neither that of the person who first hit upon the construction, nor that of him who thoroughly explained the *rationale* of the instrument. This important service to science was performed by John Kepler, whose name is famous on many accounts in the annals of philosophy, and especially by his discovery of the great law of motion respecting the heavenly bodies; which is, that the squares of their periodical times are as the cubes of their distances from the body about which they revolve; a proposition which, however, was not demonstrated before Sir Isaac Newton. Kepler was astronomer to several of the emperors of Germany; he was the associate of the celebrated astronomer Tycho Brahe, and the master of Descartes.

77 The rationale of the instrument first discovered by Kepler.

Kepler made several discoveries relating to the nature of vision; and not only explained the rationale of the telescope which he found in use, but also pointed out methods of constructing others of superior powers and more commodious application.

It was Kepler who first gave a clear explication of the effects of lenses, in making the rays of a pencil of light converge or diverge. He shewed, that a plano-convex lens makes rays that were parallel to its axis, to meet at the distance of the diameter of the sphere of convexity; but that if both sides of the lens be equally convex, the rays will have their focus at the distance of the radius of the circle, corresponding to that degree of convexity. But he did not investigate any rule for the foci of lenses unequally convex. He only says, in general, that they will fall somewhere in the medium, between the foci belonging to the two different degrees of convexity. It is to Cavallieri that we owe this investigation. He laid down this rule: As the sum of both the diameters is to one of them, so is the other to the distance of the focus. All these rules concerning convex lenses are applicable to those that are concave; with this difference, that the focus is on the contrary side of the glass, as will be particularly shewn in the second part of this treatise.

78 General reason of the effects of telescopes.

The principal effects of telescopes depend upon these plain maxims, *viz.* That objects appear larger in proportion to the angles which they subtend at the eye; and the effect is the same whether the pencils of rays, by which objects are visible to us, come directly from the objects themselves, or from any place nearer to the eye, where they may have been united so as to form an image of the object; because they issue again from those points where there is no real substance, in certain directions, in the same manner as they did from the corresponding points in the objects themselves.

In fact, therefore, all that is effected by a telescope is, first to make such an image of a distant object, by means of a lens or mirror; and then to give the eye some assistance for viewing that image as near as possible; so that the angle which it shall subtend at the eye, may be very large compared with the angle which the

the object itself would subtend in the same situation. This is done by means of an eye-glass, which so refracts the pencils of rays, as that they may afterwards be brought to their several foci by the natural humours of the eye. But if the eye was so formed as to be able to see the image with sufficient distinctness at the same distance without any eye-glass, it would appear to him as much magnified as it does to another person who makes use of a glass for that purpose, though he would not in all cases have so large a field of view.

If, instead of an eye-glass, an object, or the image of an object, be looked at thro' a small hole in a thin plate or piece of paper, held close to the eye, it may be viewed very near to the eye, and, at the same distance, the apparent magnitude of the object will be the same in both cases. For if the hole be so small as to admit but a single ray from every distinct point of the object, these rays will fall upon the retina in as many other distinct points, and make a distinct image. They are only pencils or cones of rays, which have a sensible base, as the breadth of the pupil, that are capable, by their spreading on the retina, of producing an indistinct image. As very few rays, however, can be admitted through a small hole, there will seldom be light sufficient to view any object to advantage in this manner.

If no image be actually formed by the foci of the pencils without the eye, yet if, by the help of any eye-glass, the pencils of rays shall enter the pupil, just as they would have done from any place without the eye, the visual angle will be the same as if an image had actually been formed in that place. Objects will not appear inverted through this telescope, because the pencils which form the images of them, only cross one another once, *viz.* at the object-glass, as in natural vision they do in the pupil of the eye.

79 Galilean telescope more difficult of construction than others.

Such is the telescope that was first discovered and used by philosophers; and it is remarkable that it should be of a much more difficult construction than some other kinds that have been invented since. The great inconvenience attending it is, that the field of view is exceedingly small. For since the pencils of rays enter the eye very much diverging from one another, but few of them can be intercepted by the pupil; and this inconvenience increases with the magnifying power of the telescope; so that philosophers at this day cannot help wondering, that it was possible, with such an instrument, for Galileo and others to have made the discoveries they did. It must have required incredible patience and address. No other telescope, however, than this, was so much as thought of for many years after the discovery. Descartes, who wrote 30 years after, mentions no other as actually constructed, though Kepler had suggested some.

80 Telescopes improved by Kepler.

It is to this great man that we are indebted for the construction of what we now call the *astronomical telescope*, being the best adapted for the purpose of viewing the heavenly bodies. The *rationale* of this instrument is explained, and the advantages of it are clearly pointed out, by this philosopher, in his Catoptrics; but, what is very surprising, he never actually reduced his excellent theory into practice. Montucla conjectures, that the reason why he did not make trial of his new construction was, his not being aware of the great increase of the field of view; so that being engaged in other pursuits, he might not think it of much consequence to take any pains about the construction of an instrument, which could do little more than answer the same purpose with those of which he was already possessed. He must also have foreseen, that the length of this telescope must have been greater in proportion to its magnifying power; so that it might appear to him to be upon the whole not quite so good a construction as the former.

81 His method first put in practice by Scheiner.

It was not long, however, before Kepler's new scheme of a telescope was executed; and the first person who actually made an instrument of this construction, was Father Scheiner, who has given a description of it in his *Rosa Ursina*, published in 1630. If, says he, you insert two similar lenses (that is, both convex) in a tube, and place your eye at a convenient distance, you will see all terrestrial objects inverted, indeed, but magnified and very distinct, with a considerable extent of view. He afterwards subjoins an account of a telescope of a different construction, with two convex eye-glasses, which again reverses the images, and makes them appear in their natural position. This disposition of the lenses had also been pointed out by Kepler, but had not been reduced to practice by him, any more than the former. This construction, however, answered the end but very imperfectly; and Father Rheita presently after hit upon a better construction, using three eye-glasses instead of two. This got the name of the *terrestrial telescope*, being chiefly used for terrestrial objects.

The first and last of these constructions are those which are now in common use. The proportion in which the first telescope magnifies, is as the focal length of the object-glass to that of the eye-glass.— The only difference between the Galilean telescope and the other is, that the pencils by which the extremities of any object are seen in this case, enter the eye diverging; whereas, in the other, they enter it converging; but if the sphere of concavity in the eye-glass of the Galilean telescope be equal to the sphere of convexity in the eye-glass of another telescope, their magnifying power will be the same. The concave eye-glass, however, being placed between the object-glass and its focus, the Galilean telescope will be shorter than the other, by twice the focal length of the eye-glass. Consequently, if the length of the telescopes be the same, the Galilean will have the greater magnifying power.

82 Vision most distinct in the Galilean telescopes.

Vision is also more distinct in these telescopes; owing perhaps, in part, to there being no intermediate image between the eye and the object. Besides, the eye-glass being very thin in the centre, the rays will be less liable to be distorted by irregularities in the substance of the glass. Whatever be the cause, we can sometimes see Jupiter's satellites very clearly in a Galilean telescope not more than twenty inches or two feet long; when one of four or five feet, of the common sort, will hardly make them visible.

83 Binocular telescope.

The same Father Rheita, to whom we are indebted for the useful construction of a telescope for land-objects, invented a binocular telescope, which Father Cherubin, of Orleans, endeavoured to bring into use afterwards. It consists of two telescopes fastened together, and made to point to the same object. When this instrument is well fixed, the object appears larger, and nearer to the eye, when it is seen through both the

the telescopes, than through one of them only, tho' they have the very same magnifying power. But this is only an illusion, occasioned by the stronger impression that two equal images, equally illuminated, make upon the eye. This advantage, however, is counterbalanced by the inconvenience attending the use of it.

84 Telescopes of Campani and Divini.

The first who distinguished themselves in grinding telescopic glasses were two Italians, Eustachio Divini at Rome, and Campani at Bologna, whose fame was much supperior to that of Divini, or that of any other person of his time; though Divini himself pretended, that, in all the trials that were made with their glasses, his, of a great focal distance, performed better than those of Campani, and that his rival was not willing to try them fairly, viz. with equal eye-glasses. It is generally supposed, however, that Campani realy excelled Divini, both in the goodness and the focal length of his object-glasses. It was with telescopes made by Campani that Cassini discovered the nearest satellites of Saturn. They were made by the express order of Lewis XIV. and were of 86, 100, and 136 Parisian feet focal length.

Campani sold his lenses for a great price, and took every possible method to keep his art of making them a secret. His laboratory was inaccessible to all the world, till after his death; when it was purchased by Pope Benedict XIV. who made a present of it to the academy called the *Institute*, established in that city; and by the account which M. Fougeroux has given of what he could discover from it, we learn, that (except a machine, which M. Campani constructed, to work the basons on which he ground his glasses) the goodness of his lenses depended upon the clearness of his glass, his Venetian tripoli, the paper with which he polished his glasses, and his great skill and address as a workman. It was also the general opinion at Bologna, that he owed a great part of his reputation to the secrecy and air of mystery which he affected; and that he made a great number of object-glasses which he rejected, shewing only those that were very good. He made few lenses of a very great focal distance; and having the misfortune to break one of 141 feet in two pieces, he took incredible pains to join the two parts together, which he did at length effectually, so that it was used as if it had been entire; but it is not probable that he would have taken so much pains about it, if, as he pretended, he could very easily have made another as good.

Sir Paul Neille, Dr Hooke says, made telescopes of 36 feet, pretty good, and one of 50, but not of proportional goodness. Afterwards Mr Reive first, and then Mr Cox, who were the most celebrated in England as grinders of optic glasses, made some good ones of 50 and 60 feet focal distance, and Mr Cox made one of 100; but how good, Dr Hooke could not assert.

Borelli, also, in France made object-glasses of a great focal length, one of which he presented to the royal society; but we do not find any particular account of their goodness.

85 Extraordinary object-glass made by Mr Auzout.

With respect to the focal length of telescopes, these and all others were far exceeded by M. Auzout, who made one object-glass of 600 feet focus; but he was never able to manage it, so as to make any use of it. Hartsocker is even said to have made some of a still greater focal length; but this ingenious mechanic, finding it impossible to make use of object-glasses, the focal distance of which was much less than this, when they were inclosed in a tube, contrived a method of using them without a tube, by fixing them at the top of a tree, a high wall, or the roof of a house.

86 Telescopes used without tubes.

Mr Huygens, who was also an excellent mechanic, made considerable improvements in the method of using an object-glass without a tube. He placed it at the top of a very long pole, having previously inclosed it in a short tube, which was made to turn in all directions, by means of a ball and socket. The axis of this tube he could command with a fine silken string, so as to bring it into a line with the axis of another short tube, which he held in his hand, and which contained the eye-glass. In this method he could make use of object-glasses of the greatest magnifying power, at whatever altitude his object was, and even in the zenith, provided his pole was as long as his telescope; and, to adapt it to the view of objects of different altitudes, he had a contrivance, by which he could raise or depress a stage that supported his object-glass at pleasure.

M. De la Hire made some improvement in this method of managing the object-glass, fixing it in the centre of a board, and not in a tube; but as it is not probable that this method will ever be made use of, since the discovery of both reflecting and achromatic telescopes, which are now brought to great perfection, and have even micrometers adapted to them, we shall not describe this apparatus minutely; but shall only gave a drawing of M. Huygens's pole, which, with a very short explanation, will be sufficient for the purpose. In fig. 1. *a* represents a pulley, by the help of which a stage *c*, *d*, *e*, *f*, (that supports the object-glass, *k*, and the apparatus belonging to it) may be raised higher or lower at pleasure, the whole being counterpoised by the weight *h*, fastened to a string *g*. *n*, Is a weight, by means of which the centre of gravity of the apparatus belonging to the object-glass is kept in the ball and socket, so that it may be easily managed by the string *l*, *u*, and its axis brought into a line with the eye-glass at *a*. When it was very dark, M. Huygens was obliged to make his object-glass visible by a lantern, *y*, so constructed as to throw the rays of light in a parallel direction up to it. Plate CCVIII.

The recollection of the incredible pains which philosophers of the last age took in making observations, and the great expences they were obliged to be at for that purpose, should make us sensible of the obligations we are under to such men as Gregory, Newton, and Dollond, who have enabled us to get clearer and more satisfactory views of the remote parts of our system, with much less labour and expence; and should likewise make us more diligent and solicitous to derive all the advantages we possibly can from such capital improvements.

87 Why dioptric telescopes must be made so long.

The reason why it is necessary to make the common dioptric telescopes so very long, is, that the length of them must be increased in no less a proportion than the duplicate of the increase of their magnifying power; so that, in order to magnify twice as much as before, with the same light and distinctness, the telescope must be lengthened four times; and to

to magnify thrice as much, nine times; and so on.

88 Of the apertures of refracting telescopes.

Before we mention the *reflecting telescope*, it must be observed, that M. Auzout, in a paper delivered to the Royal Society, observed, that the apertures which the object-glasses of refracting telescopes can bear with distinctness, are in about a sub-duplicate proportion to their lengths; and upon this supposition he drew up a table of the apertures proper for object-glasses of a great variety of focal lengths, from 4 inches to 400 feet. Upon this occasion, however, Dr Hooke observed, that the same glass will bear a greater or less aperture, according to the less or greater light of the object. If, for instance, he was viewing the sun, or Venus, or any of the fixed stars, he used smaller apertures: but if he wanted to view the moon by daylight; or Saturn, Jupiter, or Mars, by night; he used a larger aperture.

But the merit of all these improvements was in a manner cancelled by the discovery of the much more commodious *reflecting telescope*. For a refracting telescope, even of 1000 feet focus, supposing it possible to be made use of, could not be made to magnify with distinctness more than 1000 times; whereas a reflecting telescope, not exceeding 9 or 10 feet, will magnify 1200 times.

89 History of the reflecting telescope.

"It must be acknowledged, (says Dr Smith in his *Complete System of Optics*), that Mr James Gregory of Aberdeen was the first inventor of the reflecting telescope; but his construction is quite different from Sir Isaac Newton's, and not nearly so advantageous."

But, according to Dr Pringle, Mersennus was the man who entertained the first thought of a reflector. A telescope with specula he certainly proposed to the celebrated Descartes many years before Gregory's invention, though indeed in a manner so very unsatisfactory, that Descartes, who had given particular attention to the improvement of the telescope, was so far from approving the proposal, that he endeavoured to convince Mersennus of its fallacy (A). Dr Smith, it appears, had never perused the two letters of Descartes to Mersennus which briefly touch on that subject.

Again, as to his assertion, that Gregory's construction was not nearly so advantageous as Newton's, it may be accounted for from his having set it down early in the composition of his work, and forgetting to qualify it afterwards, when, before the publication, he had received pretty sure information to the contrary. Or perhaps he was influenced by the example of Dr Bradley, who had been a most successful observer, and yet had always preferred the Newtonian telescope to the other. But we must certainly adjudge the superiority to the latter, as that is now, and has been for several years past, the only instrument of the kind in request.

Gregory, a young man of an uncommon genius, was led to the invention, in seeking to correct two imperfections of the common telescope: the first was its too great length, which made it less manageable; the second, the incorrectness of the image. Mathematicians had demonstrated, that a pencil of rays could not be collected in a single point by a spherical lens; and also, that the image transmitted by such a lens would be in some degree incurvated. These inconveniences he believed would be obviated by substituting for the object-glass a metallic speculum, of a parabolic figure, to receive the image, and to reflect it towards a small speculum of the same metal: this again was to return the image to an eye-glass placed behind the great speculum, which for that purpose was to be perforated in its centre. This construction he published in 1663, in his *Optica Promota*. But as Gregory, as he himself declares, was endowed with no mechanical dexterity, nor could find any workman capable of realizing his invention, after some fruitless attempts in that way he was obliged to give up the pursuit: and probably, had not some new discoveries been made in light and colours, a reflecting telescope would never more have been thought of, considering the difficulty of the execution, and the small advantages that could accrue from it, deducible from the principles of optics that were then known.

But Newton, whose happy genius for experimental knowledge was equal to that for geometry, happily interposed, and saved this noble invention from well-nigh perishing in its infant-state. He likewise at an early period of life had applied himself to the improvement of the telescope; but imagining that Gregory's specula were neither very necessary, nor likely to be executed, he began with prosecuting the views of Descartes, who aimed at making a more perfect image of an object, by grinding lenses, not to the figure of a sphere, but to that of one of the conic sections. Now, whilst he was thus employed, three years after Gregory's publication, he happened to take to the examination of the colours formed by a prism, and having by the means of that simple instrument discovered the different refrangibility of the rays of light, he then perceived that the errors of telescopes, arising from that cause alone, were some hundred times greater than such as were occasioned by the spherical figure of lenses. This circumstance, forced, as it were, Newton to fall into Gregory's track, and to turn his thoughts to reflectors. "The different refrangibility of the rays of light (says he, in a letter to Mr Oldenburg, secretary to the Royal Society, dated in Feb. 1672), made me take reflections into consideration; and finding them regular, so that the angle of reflection of all sorts of rays was equal to the angle of incidence, I understood, that by their mediation optic instruments might be brought to any degree of perfection imaginable, providing a reflecting substance could be found which would polish as finely as glass, and reflect as much light as glass transmits, and the art of communicating to it a parabolic figure be also obtained. Amidst these thoughts I was forced from Cambribge by the intervening plague, and it was more than two years before I proceeded further."

It appears, then, that if Newton was not the first inventor of the reflecting telescope, he was the main and effectual inventor. By the force of his admirable genius, he fell upon this new property of light; and thereby found, that all lenses, of whatever figure, would be affected more or less with such prismatic aberrations of

(A) *Lettres de Descartes, tome* ii. printed at Paris in 1657, lett. 29. and 32. See this point discussed by two learned and candid authors, M. le Roi in the *Encyclopedie*, under the article *Telescope*, and M. Montecula in *Hist. des Mathem. tome* ii. p. 644.

of the rays as would be an insuperable obstacle to the perfection of a dioptric telescope.

It was towards the end of 1668, or in the beginning of the following year, when Newton, being thus obliged to have recourse to reflectors, and not relying on any artificer for making his specula, set about the work himself, and early in the year 1672 completed two small reflecting telescopes. In these he ground the great speculum into a spherical concave; not but that he approved of the parabolic form proposed by Gregory, though he found himself unable to accomplish it. In the letter that accompanied one of these instruments which he presented to the Society, he writes, "that though he then despaired of performing that work (to wit, the parabolic figure of the great speculum) by geometrical rules, yet he doubted not but that the thing might in some measure be accomplished by mechanical devices."

Not less did the difficulty appear to find a metallic substance that would be of a proper hardness, have the fewest pores, and receive the smoothest polish: a difficulty in truth which he deemed almost unsurmountable, when he considered, that every irregularity in a reflecting surface would make the rays of light stray five or six times more out of their due course, than the like irregularities in a refracting one. In another letter, written soon after, he tells the secretary, "that he was very sensible that metal reflects less light than glass transmits; but as he had found some metallic substances to be more strongly reflective than others, to polish better, and to be freer from tarnishing than others, so he hoped that there might in time be found out some substances much freer from these inconveniences than any yet known." Newton therefore laboured till he found a composition that answered in some degree, and left it to those who should come after him to find a better, and presented a reflecting telescope to the Royal Society; from whom he received such thanks as were due to so curious and valuable a present. And Huygens, one of the greatest geniuses of the age, and himself a distinguished improver of the refractor, no sooner was informed by Mr Oldenburg of the discovery, than he wrote in answer, "that it was an admirable telescope; and that Mr Newton had well considered the advantage which a concave speculum had above convex glasses in collecting the parallel rays, which according to his own calculation was very great: Hence that Mr Newton could give a far greater aperture to that speculum than to an object-glass of the same distance of focus, and consequently much more magnify in his way than by an ordinary telescope: Besides, that by the reflector he avoided an inconvenience inseparable from object-glasses, which was the obliquity of both their surfaces, which vitiated the refraction of the rays that pass towards the sides of the glass, and did more hurt than men were aware of: Again, that by the mere reflection of the metalline speculum there were not so many rays lost as in glasses, which reflected a considerable quantity by each of their surfaces, and besides intercepted many of them by the obscurity of their matter: That the main business would be, to find a matter for this speculum that would bear as good and even a polish as glass. Lastly, he believed that Mr Newton had not been without considering the advantage which a parabolic speculum would have over a spherical one in this construction; but had despaired, as he himself had done, of working other surfaces than spherical ones with due exactness." Huygens was not satisfied with thus expressing to the society his high approbation of the late invention; but drew up a favourable account of the new telescope, which he caused to be published in the *Journal des Scavans* for the year 1672, and by that channel it was soon known over Europe.

But how excellent soever the contrivance was; how well soever supported and announced to the public; yet whether it was that the artists were deterred by the difficulty and labour of the work, or that the discoveries even of a Newton were not to be exempted from the general fatality attending great and useful inventions, *the making a slow and vexatious progress to the authors*; the fact is, that, excepting an unsuccessful attempt which the society made, by employing an artificer to imitate the Newtonian construction, but upon a larger scale, and a disguised Gregorian telescope, set up by Cassegrain abroad as a rival to Newton's, and that in theory only (for it never was put in execution by the author), no reflector was heard of for nearly half a century after. But when that period was elapsed, a reflecting telescope was at last produced to the world of the Newtonian construction by Dr Hadley, which the author had the satisfaction to find executed in such a manner as left no room to fear that the invention would any longer continue in obscurity.

This memorable event was owing to the genius, dexterity, and application, of Mr Hadley the inventor of the reflecting quadrant, another most valuable instrument. The two telescopes which Newton had made were but six inches long, were held in the hand for viewing objects, and in power were compared to a six-feet refractor; whereas Hadley's was above five feet long, was provided with a well-contrived apparatus far managing it, and equalled in performance the famous aerial telescope of Huygens of 123 feet in length. Excepting as to the manner of making the specula, we have, in the transactions of 1723, a complete description, with a figure, of this telescope, together with that of the machine for moving it; but, by a strange omission, Newton's name is not once mentioned in that paper, so that any person not acquainted with the history of the invention, and reading that account only, might be apt to conclude that Hadley had been the sole contriver of it.

The same celebrated artist, after finishing two telescopes of the Newtonian construction, accomplished a third in the Gregorian way; but, it would seem, less successfully, by Dr Smith's declaring so strongly in favour of the other. Mr Hadley spared no pains to instruct Mr Molyneux and the reverend Dr Bradley; and when those gentlemen had made a sufficient proficiency in the art, being desirous that these telescopes should become more public, they liberally communicated to some of the principal instrument-makers of London the knowledge they had acquired from him. Now such scholars, as it is easy to imagine, soon advanced beyond their masters, and completed reflectors by other and better methods than what had been taught them.

Cer-

Certain it is, at leaft, that Mr James Short, as early as the year 1734, had fignalized himfelf at Edinburgh by his work of this kind. Mr Maclaurin wrote that year to Dr Jurin, " that Mr Short, who had begun with making glafs fpecula, was then applying himfelf to improve the metallic; and that, by taking care of the figure, he was enabled to give them larger apertures than others had done; and that upon the whole they furpaffed in perfection all that he had feen of other workmen." He added, " that Mr Short's telefcopes were all of the Gregorian conftruction; and that he had much improved that excellent invention." This character of excellence Mr Short maintained to the laft; and with the more facility, as he had been well grounded both in the geometrical and philofophical principles of optics, and upon the whole was a moft intelligent perfon in whatever related to his profeffion. It was fuppofed he had fallen upon a method of giving the parabolic figure to his great fpeculum; a point of perfection that Gregory and Newton had wifhed for, but defpaired of attaining; and that Hadley had never, as far as we know, attempted, either in his Newtonian or Gregorian telefcope. Mr Short indeed faid he had acquired that faculty, but never would tell by what peculiar means he effected it; fo that the fecret of working that configuration, whatever it was, as far as it then appeared, died with that ingenious artift. Mr Mudge, however, hath lately realized the expectation of Sir Ifaac Newton, who, above 100 years ago, prefaged that the public would one day poffefs a parabolic fpeculum, not accomplifhed by mathematical rules, but by mechanical devices.

This was a *defideratum*, but it was not the only want fupplied by this gentleman: he has taught us likewife a better compofition of metals for the fpecula, how to grind them better, and how to give them a finer polifh; and this laft part, (namely, the polifh), he remarks, was the moft difficult and effential of the whole operation. " In a word, (fays Sir John Pringle), I am of opinion, there is no optician in this great city (which hath been fo long and fo juftly renowned for ingenious and dextrous makers of every kind of mathematical inftruments) fo partial to his own abilities as not to acknowledge, that, however fome parts of the mechanical procefs now difclofed might have been known before by individuals of the profeffion, yet that Mr Mudge hath opened to them all fome new and important lights, and upon the whole hath greatly improved the art of making reflecting telefcopes."

90 Account of Mr Dollond's improvements

The greateft improvement in *refracting* telefcopes is that of Mr Dollond, of which an account has already been given in a preceding fection, wherein his difcoveries in the fcience of Optics were explained. But, befides the obligation we are under to him for correcting the abberration of the rays of light in the focus of object-glaffes, arifing from their different refrangibility, he made another confiderable improvement in telefcopes, viz. by correcting, in a great meafure, both this kind of aberration, and alfo that which arifes from the fpherical form of lenfes, by an expedient of a very different nature; viz. increafing the number of eye-glaffes.

If any perfon, fays he, would have the vifual angle of a telefcope to contain 20 degrees, the extreme pencils of the field muft be bent or refracted in an angle of 10 degrees; which, if it be performed by one eye-glafs, will caufe an aberration from the figure, in proportion to the cube of that angle; but if two glaffes are fo proportioned and fituated, as that the refraction may be equally divided between them, they will each of them produce a refraction equal to half the required angle; and therefore, the aberration being in proportion to the cube of half the angle taken twice over, will be but a fourth part of that which is in proportion to the cube of the whole angle; becaufe twice the cube of 1 is but $\frac{1}{4}$ of the cube of 2; fo the aberration from the figure, where two eye-glaffes are rightly proportioned, is but a fourth of what it muft unavoidably be where the whole is performed by a fingle eye-glafs. By the fame way of reafoning, when the refraction is divided between three glaffes, the aberration will be found to be but the ninth part of what would be produced from a fingle glafs; becaufe three times the cube of 1 is but one-ninth of the cube of 3. Whence it appears, that by increafing the number of eye-glaffes, the indiftinctnefs which is obferved near the borders of the field of a telefcope may be very much diminifhed, though not entirely taken away.

The method of correcting the errors arifing from the different refrangibility of light is of a different confideration from the former. For, whereas the errors from the figure can only be diminifhed in a certain proportion according to the number of glaffes, in this they may be entirely corrected by the addition of only one glafs; as we find in the aftronomical telefcope, that two eye-glaffes, rightly proportioned, will caufe the edges of objects to appear free from colours, quite to the borders of the field. Alfo in the day-telefcope, where no more than two eye-glaffes are abfolutely neceffary for erecting the object, we find, that by the addition of a third, rightly fituated, the colours, which would otherwife make the image confufed, are entirely removed. This, however, is to be underftood with fome limitation: for though the different colours into which the extreme pencils muft neceffarily be divided by the edges of the eye-glaffes, may in this manner be brought to the eye in a direction parallel to each other, fo as, by the humours of the eye, to be made to converge to a point on the retina; yet, if the glaffes exceed a certain length, the colours may be fpread too wide, to be capable of being admitted thro' the pupil or aperture of the eye; which is the reafon, that in long telefcopes, conftructed in the common manner, with three eye-glaffes, the field is always very much contracted.

Thefe confiderations firft fet Mr Dollond on contriving how to enlarge the field, by increafing the number of eye-glaffes without any hindrance to the diftinctnefs or brightnefs of the image; and though others had been about the fame work before, yet, obferving that fome five-glafs telefcopes which were then made would admit of farther improvement, he endeavoured to conftruct one with the fame number of glaffes in a better manner; which fo far anfwered his expectations, as to be allowed by the beft judges to be a confiderable improvement on the former.

Encouraged by this fuccefs, he refolved to try if he could

could not make some farther enlargement of the field, by the addition of another glass, and by placing and proportioning the glasses in such a manner as to correct the aberrations as much as possible, without any detriment to the distinctness; and at last he obtained as large a field as is convenient or necessary, and that even in the longest telescopes that can be made.

These telescopes with six glasses having been well received, and some of them being gone into foreign parts, it seemed a proper time to the author to settle the date of his invention; on which account he drew up a letter, which he addressed to Mr Short, and which was read at the Royal Society, March 1, 1753.

91 Mr Smith's proposal to shorten telescopes.

Various other attempts were made about this time to shorten and otherwise improve telescopes. Among these we must just mention that of Mr Caleb Smith, who, after giving much attention to the subject, thought that he had found it possible to rectify the errors which arise from the different degrees of refrangibility, on the principle that the sines of refraction, or rays differently refrangible, are to one another in a given proportion, when their sines of incidence are equal; and the method which he proposed for this purpose was to make the speculums of glass instead of metal, the two surfaces having different degrees of concavity. But we do not find that his scheme was ever executed; nor is it probable, for reasons which have been mentioned, that any advantage could be made of it.

92 Equatorial telescope, or portable observatory

To Mr Short we are indebted for the excellent contrivance of an equatorial telescope, or, as he likewise called it, a *portable observatory;* for with it pretty accurate observations may be made with very little trouble, by those who have no building adapted to the purpose. The instrument consists of an ingenious piece of machinery, by the help of which a telescope mounted upon it may be directed to any degree of right ascension or declination, so that the place of any of the heavenly bodies being known, they may be found without any trouble, even in the day-time. Also, being made to turn parallel to the equator, any object is easily kept in view, or recovered, without moving the eye from its situation. By this instrument, Mr Short informs us, that most of the stars of the first and second magnitude have been seen even at mid-day, and the sun shining bright; as also Mercury, Venus, and Jupiter. Saturn and Mars are not so easy to be seen, on account of the faintness of their light, except when the sun is but a few hours above the horizon. This particular effect depends upon the telescope excluding almost all the light, except what comes from the object itself, and which might otherwise efface the impression made by its weaker light upon the eye. Any telescope of the same magnifying power would have the same effect, could we be sure of pointing it right. For the same reason, also, it is that stars are visible in the day-time from the bottom of a deep pit.

93 How to observe the stars in the day-time.

In order to enable us to see the fixed stars in the day-time, it is necessary to exclude the extraneous light as much as possible. For this reason the greater magnifying power of any telescope is used, the more easily a fixed star will be distinguished in the day-time; the light of the star remaining the same in all magnifying powers of the same telescope, but the ground upon which it is seen becoming darker by increasing the magnifying power; and the visibility of a star depends very much upon the difference between its own light and that of the ground upon which it is seen. A fixed star will be very nearly equally visible with telescopes of very different apertures, provided the magnifying power remains the same.

If a comet, or any other heavenly body, be viewed through this equatorial telescope, properly rectified, it is seen immediately by the help of the same machinery what is its true place in the heavens. Other astronomical problems may also be solved by it, with great ease and certainty. But a particular description of its construction and uses, will be afterwards given.

94 Mr Epinus's proposal for bending the tubes of telescopes.

M. Æpinus proposes to bend the tubes of long telescopes at right angles, fixing a plane mirror in the angle, in order to make them more commodious for viewing objects near the zenith of the observer; and he gives particular instructions how to make them in this form, especially when they are furnished with micrometers. We are also informed that a little plane speculum is sometimes placed betwixt the last eye-glass and the eye in the reflecting telescopes, at an angle of 45°, for the same purpose.

95 History of microscopes

The invention of MICROSCOPES was not much later than that of telescopes; and, according to Borellus, whose account we do not find to have been called in question by any person, we are indebted for them to the same author, at least to Z. Jansen, in conjunction with his son; and for this latter favour we may, perhaps, be considered as under more obligation to them than for the former, the microscope having more various and extensive uses, with respect to philosophy, than the telescope. In our ideas, however, it appears something greater, and more extraordinary, to be able to see objects too distant to be perceived by the naked eye, than those that are too near to be seen by us; and therefore there is more of the sublime in the telescope than the microscope. These two instruments, though different in their application, are notwithstanding very similar; as both of them assist us in the discovery of objects that we must otherwise have remained unacquainted with, by enlarging the angle which they subtend at the eye.

The Jansens, however, have not always enjoyed, undisturbed, that share of reputation to which they seem to be intitled, with respect either to the telescope or the microscope. The discovery of the latter, in particular, has generally been considered as more uncertain than that of the former. All that many writers say we can depend upon is, that microscopes were first used in Germany about the year 1621. Others say positively, that this instrument was the contrivance of Cornelius Drebell, no philosopher, but a man of curiosity and ingenuity, who also invented the thermometer.

According to Borellus, Zacharias Jansen and his son presented the first microscopes they had constructed to prince Maurice, and Albert archduke of Austria. William Borell, who gives this account in a letter to his brother Peter, says, that when he was ambassador in England, in 1619, Cornelius Drebell, with whom he was intimately acquainted, shewed him a microscope, which he said was the same the archduke had given him, and had been made by Jansen himself.

This

This inftrument was not fo fhort as they are generally made at prefent, but was fix feet long, confifting of a tube of gilt copper, an inch in diameter, fupported by three brafs pillars in the fhape of dolphins, on a bafe of ebony, on which the fmall objects were placed.

96 Microfcope made by Janfen. This telefcope was evidently a compound one, or rather fomething betwixt a telefcope and a microfcope, what we fhould now, perhaps, choofe to call a *megalafcope;* fo that it is poffible that fingle microfcopes might have been known, and in ufe, fome time before: but perhaps nobody thought of giving that name to fingle lenfes; though, from the firft ufe of lenfes, they could not but have been ufed for the purpofe of magnifying fmall objects. In this fenfe we have feen, that even the ancients were in poffeffion of microfcopes; and it appears from Jamblicus and Plutarch, quoted by Dr Rogers, that they gave fuch inftruments as they ufed for this purpofe the name of *dioptra*. As fpectacles were certainly in ufe long before the invention of telefcopes, one can hardly help concluding, that lenfes muft have been made fmaller, and more convex, for the purpofe of magnifying of minute objects; efpecially as the application of this kind of microfcope was nearly the fame with that of a fpectacle glafs, both of them being held clofe to the eye. At what time lenfes were made fo fmall as we now generally ufe them for magnifying in fingle microfcopes, we have not found. But as this muft neceffarily have been done gradually, the only proper object of inquiry is the invention of the double, or compound microfcope; and this is clearly given, by the evidence of Borellus above-mentioned, to Zacharias Janfen, the inventor of the telefcope, or his fon.

The invention of compound microfcopes is claimed by the fame Fontana who claimed the difcovery of telefcopes; and though he did not publifh any account of this improvement till the year 1646 (nothwithftanding he pretended to have made the difcovery in 1618), Montucla, not having attended perhaps to the teftimony of Borellus, is willing to allow his claim, as he thought there was no other perfon who feemed to have any better right to it.

97 By Divini. Euftachio Divini made microfcopes with two common object-glaffes, and two plano-convex eye-glaffes joined together on their convex fides fo as to meet in a point. The tube in which they were inclofed was as big as a man's leg, and the eye-glaffes almoft as broad as the palm of a man's hand. Mr Oldenburg, fecretary to the royal fociety, received an account of this inftrument from Rome, and read it at one of their meetings, Auguft 6, 1668.

98 By Hartfocker. It was in this period that Hartfocker improved fingle microfcopes, by ufing fmall globules of glafs, made by melting them in the flame of a candle, inftead of the lenfes which had before been made ufe of for that purpofe. By this means he firft difcovered the *animalcula in femine mafculino*, which gave rife to a new fyftem of generation. A microfcope of this kind, confifting of a globule of $\frac{1}{10}$ of an inch in diameter, M. Huygens demonftrated to magnify 100 times; and fince it is eafy to make them of lefs than half a line in diameter, they may be made to magnify 300 times. Were it not for the difficulty of applying objects to thefe magnifiers, the want of light, and the fmall field of diftinct vifion, they would certainly have been the moft perfect of all microfcopes.

99 By Leeuwenhoek. But no man diftinguifhed himfelf fo much by microfcopical difcoveries as the famous M. Leeuenhoek, though he ufed only fingle lenfes with fhort foci, preferring diftinctnefs of vifion to a large magnifying power.

M. Leeuwenhoek's microfcopes were all fingle ones, each of them confifting of a fmall double convex-glafs, fet in a focket between two filver plates rivetted together, and pierced with a fmall hole; and the object was placed on the point of a needle, fo contrived, as to be placed at any diftance from the lens. If the objects were folid, he faftened them with glue; and if they were fluid, or on other accounts required to be fpread upon glafs, he placed them on a fmall piece of Mufcovy talc, or glafs blown very thin; which he afterwards glued to his needle. He had, however, a different apparatus for viewing the circulation of the blood, which he could fix to the fame microfcopes.

The greateft part of his mifcrofcopes M. Leeuwenhoek bequeathed to the royal fociety. They were contained in a fmall Indian cabinet, in the drawers of which were 13 little boxes, or cafes, in each of which were two microfcopes, neatly fitted up in filver; and both the glafs and the apparatus were made with his own hands.

The glafs of all thefe lenfes is exceedingly clear, but none of them magnifies fo much as thofe globules which are frequently ufed in other microfcopes; but Mr Folkes, who examined them, thought that they fhewed objects with much greater diftinctnefs, which M. Leeuwenhoek principally valued. His difcoveries, however, are to be afcribed not fo much to the goodnefs of his glaffes, as to his great judgment, acquired by long experience, in ufing them. He alfo particularly excelled in his manner of preparing objects for being viewed to the moft advantage.

Mr Baker, who alfo examined M. Leeuwenhoek's microfcopes, and made a report concerning them to the royal fociety, found that the greateft magnifier among them enlarged the diameter of an object about 160 times, but that all the reft fell much fhort of that power; fo he concluded that M. Leeuenhoek muft have had other microfcopes of a much greater magnifying power for many of his difcoveries. And it appears, he fays, by many circumftances, that he had fuch microfcopes.

It appears from M. Leeuwenhoek's writings, that he was not unacquainted with the method of viewing opaque objects by means of a fmall concave reflecting mirror, which was afterwards improved by M. Lieberkhun. For, after defcribing his apparatus for viewing eels in glafs tubes, he adds, that he had an inftrument to which he fcrewed a microfcope fet in brafs, upon which microfcope he faftened a little difh of brafs, probably that his eye might be thereby affifted to fee objects better; for he fays he had filed the brafs which was round his microfcope as bright as he could, that the light, while he was viewing objects, might be reflected from it as much as poffible. This microfcope, with its difh, (of which an exact copy, taken from the picture in his works, may be feen, Plate CCVIII. fig. 2.) feems fo like our opaque microfcope, with its filver fpeculum, that it may well be fuppofed to have given the hint to the ingenious inven-

ventor of it, provided he ever attended to it.

100 Wilſon's microſcope.

In 1702, Mr Wilſon made ſeveral ingenious improvements in the method of uſing ſingle magnifiers, for the purpoſe of viewing tranſparent objects; and they have been ſo generally approved, that hardly any other method is made uſe of at this day. The capital advantage attending this microſcope conſiſts in its being furniſhed with a pretty large lens, to throw light upon the objects, and alſo with a fine ſcrew and ſpring, to bring them nearer, or remove them farther from the magnifier at pleaſure. This microſcope is alſo a neceſſary part of the ſolar microſcope, invented afterwards.

101 Adams's method of making globules for large magnifiers.

In 1710, Mr Adams gave to the Royal Society the following account of his method of making ſmall globules for large magnifiers. He took a piece of fine window-glaſs, and cut it with a diamond into as many lengths as he thought proper, not exceeding $\frac{1}{8}$ of an inch in breadth; then, holding one of them between the fore-finger and thumb of each hand over a very fine flame, till the glaſs began to ſoften, he drew it out till it was as fine as a hair, and broke; then putting each of the ends into the pureſt part of the flame, he had two globules preſently, which he could make larger or leſs at pleaſure. If they were held a long time in the flame, they would have ſpots in them, ſo that he drew them out preſently after they became round. The ſtem he broke off as near to the globule as he could, and lodging the remainder between the plates, in which holes were drilled exactly round, the microſcope, he ſays, performed to admiration. Through theſe magnifiers, he ſays, that the ſame thread of very fine muſlin appeared three or four times bigger than it did in the largeſt of Mr Wilſon's magnifiers.

102 Temporary microſcopes by Mr Grey.

The ingenious Mr Grey hit upon a very eaſy expedient to make very good temporary microſcopes, at a very little expence. They conſiſt of nothing but very ſmall drops of water, taken up with a point of a pin, and put into a ſmall hole made in a piece of metal. Theſe globules of water do not, indeed, magnify ſo much as thoſe which are made of glaſs of the ſame ſize, becauſe the refractive power of water is not ſo great; but the ſame purpoſe will be anſwered nearly as well by making them ſomewhat ſmaller.

The ſame ingenious perſon, obſerving that ſmall heterogeneous particles incloſed in the glaſs of which microſcopes are made, were much magnified when thoſe glaſſes were looked through, thought of making his microſcopes of water that contained living animalcula, to ſee how they would look in this new ſituation; and he found his ſcheme to anſwer even beyond his utmoſt expectation, ſo that he could not even account for their being magnified ſo much as they were: for it was much more than they would have been magnified if they had been placed beyond the globule, in the proper place for viewing objects. But Montucla obſerves, that, when any object is incloſed within this ſmall tranſparent globule, the hinder-part of it acts like a concave mirror, provided they be ſituated between that ſurface and the focus; and that, by this means, they are magnified above $3\frac{1}{2}$ times more than they would have been in the uſual way.

After the happy execution of the reflecting teleſcope, it was natural to expect that attempts would alſo be made to render a ſimilar ſervice to microſcopes. Accordingly we find two plans of this kind. The firſt was that of Dr Robert Barker. His inſtrument differs in nothing from the reflecting teleſcope, excepting the diſtance of the two ſpeculums, in order to adapt it to thoſe pencils of rays which enter the teleſcope diverging; whereas they come from very diſtant objects nearly parallel to each other.

103 Dr Barker's reflecting microſcope.

This microſcope is not ſo eaſy to manage as the common ſort. For viſion by reflection, as it is much more perfect, ſo it is far more difficult than that by refraction. Nor is this microſcope ſo uſeful for any but very ſmall or tranſparent objects. For the object, being between the ſpeculum and image, would, if it were large and opaque, prevent a due reflection.

104 Dr Smith's reflecting microſcope.

In Dr Smith's reflecting microſcope there are two reflecting mirrors, one concave and the other convex, and the image is viewed by a lens.

This microſcope, though far from being executed in the beſt manner, performed, Dr Smith ſays, nearly as well as the very beſt refracting microſcopes; ſo that he did not doubt but that it would have excelled them, if it had been executed properly. Dr Smith's own account of this inſtrument may be ſeen in his Optics, Remarks, p. 94.

105 Solar microſcope, and that for opaque objects.

In 1738 or 1739, M. Lieberkuhn made two capital improvements in microſcopes, by the invention of the *ſolar microſcope*, and the *microſcope for opaque objects*. When he was in England in the winter of 1739, he ſhewed an apparatus of his own making, for each of theſe purpoſes, to ſeveral gentlemen of the Royal Society, as well as to ſome opticians, particularly Mr Cuff in Fleet-ſtreet, who took great pains to improve them.

The ſolar microſcope, as made by Mr Cuff, was compoſed of a tube, a looking-glaſs, a convex lens, and a Wilſon's microſcope. Of this, and of another conſtructed by Mr Martin, a particular deſcription will be afterwards given.

The microſcope for opaque objects remedies the inconvenience of having the dark ſide of an object next the eye. For by means of a concave ſpeculum of ſilver, highly poliſhed, in the centre of which a magnifying lens is placed, the object is ſo ſtrongly illuminated that it may be examined with all imaginable eaſe and pleaſure. A convenient apparatus of this kind, with four different ſpeculums and magnifiers of different powers, was brought to perfection by Mr Cuff.

M. Lieberkuhn made conſiderable improvements in his ſolar microſcope, particularly in adapting it to the view of opaque objects; but in what manner this end was effected, M. Æpinus, who was highly entertained with the performance, and who mentions the fact, was not able to recollect; and the death of the ingenious inventor prevented his publiſhing any account of it himſelf. M. Æpinus invites thoſe perſons who came into the poſſeſſion of M. Lieberkuhn's apparatus to publiſh an account of this inſtrument; but it doth not appear that his method was ever publiſhed.

This improvement of M. Lieberkuhn's induced M. Æpinus himſelf to attend to the ſubject; and by this means produced a very valuable improvement in this inſtrument. For by throwing the light upon the foreſide of any object by means of a mirror, before it is tranſmitted through the object-lens, all kinds of objects are equally well repreſented by it.

M.

106 Reflected light introduced into the microscope and magic lantern.

M. Euler proposed a scheme to introduce vision by reflected light into the magic lantern and solar microscope, by which many inconveniences to which those instruments are subject, might be avoided. For this purpose, he says, that nothing is necessary but a large concave mirror, perforated as for a telescope; and that the light be so situated, that none of it may pass directly through the perforation, so as to fall on the images of the objects upon the screen. He proposes to have four different machines, for objects of different sizes; the first for those of six feet long, the second for those of one foot, the third for those of two inches, and the fourth for those of two lines. An idea of this contrivance is given in Plate CCVIII. fig. 3. in which OD represents the concave mirror, E the object, *l*, *l* the lights, and A the lens, through which the rays are transmitted to the screen.

Several improvements were made in the apparatus to the solar microscope, as adapted to view opaque objects, by M. Zeiher, who made one construction for the larger kind of objects, and another for the small ones.

107 Mr Martin's improvement in the solar microscope.

Mr Martin having constructed a solar microscope of a larger size than common, for his own use, the illuminating lens being $4\frac{1}{2}$ inches in diameter, and all the other parts of the instrument in proportion, found, that by the help of an additional part, which he does not describe, he could see even opaque objects very well. If he had made the lens any larger, he was aware that the heat produced at the focus would be too great for the generality of objects to bear. The expence of this instrument, he says, does not much exceed the price of the common solar microscope.

108 Di Torres's extraordinary magnifying microscope.

The smallest globules, and consequently the greatest magnifiers, for microscopes, that have yet been executed, were made by T. Di Torre of Naples, who, in 1765, sent four of them to the Royal Society. The largest of them was only two Paris points in diameter, and it was said to magnify the diameter of an object 640 times. The second was the size of one Paris point, and the third was no more than half of a Paris point, or the 144th part of an inch in diameter, and was said to magnify the diameter of an object 2560 times. One of these globules was wanting when they came into the hands of Mr Baker, to whose examination they were referred by the Royal Society. This gentleman, so famous for his skill in microscopes, and his extraordinary expertness in managing them, was not able to make any use of these. With that which magnifies the least, he was not able to see any object with satisfaction; and he concludes his account with expressing his hopes only, that, as his eyes had been much used to microscopes, they were not injured by the attention he had given to them, though he believed there were few persons who would not have been blinded by it.

109 Could not be used by Mr Baker.

The construction of a telescope with six eye-glasses led M. Euler to a similar construction of microscopes, by introducing into them six lenses, one of which admits of so small an aperture, as to serve, instead of a diaphragm, to exclude all foreign light, though, as he says, it neither lessens the field of view, nor the brightness of objects.

110 Difficulties attending the construction of dioptric instruments.

The improvement of all dioptric instruments is greatly impeded by inequalities in the substance of the glass of which they are made; but though many attempts have been made to make glass without that imperfection, none of them have been hitherto quite effectual. M. A. D. Merklein, having found some glass which had been melted when a building was on fire, and which proved to make excellent object-glasses for telescopes, concluded that its peculiar goodness arose from its not having been disturbed when it was in a fluid state; and therefore he proposed to take the metal out of the furnace in iron vessels, of the same form that was wanted for the glass; and after it had been perfectly fluid in those vessels, to let it stand to cool, without any disturbance. But this is not always found to answer.

PART II. Theory of Optics.

This part of the science contains all that hath been discovered concerning the various motions of the rays of light either through different mediums, or when reflected from different substances in the same medium. It contains also the rationale of every thing which hath been discovered with regard to vision; the optical deceptions to which we are liable; and, in short, ought to give the reason of all the known optical phenomena.—The science is commonly divided into three parts, viz. dioptrics, which contains the laws of refraction, and the phenomena depending upon them; catoptrics, which contains the laws of reflection, and the phenomena which depend on them; and lastly chromatics, which treats of the phenomena of colour. But this definition is of no use in a treatise of Optics, as most of the phenomena depend both on refraction and reflection; colour itself not excepted. For this reason we have not followed that method of dividing our subject; but have explained the particular laws of refraction and reflection, afterwards showing how, by these, the most remarkable optical phenomena may be accounted for.

Sect. I. *Of the properties of Light in general.*

Without entering into any repetition of the controversies concerning the nature of Light, which are fully set forth under that article, we shall here give a brief description of its properties considered as the subject of the optical science, and which hold good in all cases without regard to other theories.

Every visible body emits or reflects inconceivably small particles of matter from each point of its surface, which issue from it continually (not unlike sparks from a coal) in straight lines and in all directions. These particles entering the eye, and striking upon the retina, (a nerve expanded on the back part of the eye to receive their impulses), excite in our minds the idea of light. And as they differ in substance, density, velocity, or magnitude, they produce in us the ideas of different colours; as will be explained in its proper place.

That the particles which constitute light are exceedingly small, appears from hence, *viz.* that if a hole be made through a piece of paper with a needle, rays of

Of Light.

of light from every object on the farther side of it are capable of passing through it at once without the least confusion; for any one of those objects may as clearly be seen through it, as if no rays passed through it from any of the rest. Further, if a candle is lighted, and there be no obstacle in the way to obstruct the progress of its rays, it will fill all the space within two miles of it every way with luminous particles, before it has lost the least sensible part of its substance thereby.

That these particles proceed from every point of the surface of a visible body, and in all directions, is clear from hence, *viz.* because wherever a spectator is placed with regard to the body, every point of that part of the surface which is turned towards him is visible to him. That they proceed from the body in right lines, we are assured, because just so many and no more will be intercepted in their passage to any place by an interposed object, as that object ought to intercept, supposing them to come in such lines.

The velocity with which they proceed from the surface of the visible body is no less surprising than their minuteness: the method whereby philosophers estimate their swiftness, is by observations made on the eclipses of Jupiter's satellites; which eclipses to us appear about seven minutes sooner than they ought to do by calculation, when the earth is placed between the sun and him, that is, when we are nearest to him; and as much later, when the sun is between him and us, at which time we are farthest from him; from whence it is concluded, that they require about seven minutes to pass over a space equal to the distance between the sun and us, which is about 95,000,000 of miles.

A stream of these particles issuing from the surface of a visible body in one and the same direction, is called a *ray of light*.

As rays proceed from a visible body in all directions, they necessarily become thinner and thinner, continually spreading themselves as they pass along into a larger space, and that in proportion to the squares of their distances from the body; that is, at the distance of two spaces, they are four times thinner than they are at one; at the distance of three spaces, nine times thinner, and so on: the reason of which is, because they spread themselves in a twofold manner, *viz.* upwards and downwards, as well as sidewise.

The particles of light are subject to the laws of attraction of cohesion, like other small bodies; for if a ray of light be made to pass by the edge of a knife, it will be diverted from its natural course, and be inflected towards the edge of the knife. The like inflection happens to a ray when it enters obliquely into a denser or rarer substance than that in which it was before, in which case it is said to be refracted; the laws of which refraction are the subject of the following section.

Sect. II. *Of Refraction.*

111 Refraction defined.

Light, when proceeding from a luminous body, without being reflected from any opaque substance, or inflected by passing very near one, is invariably found to proceed in straight lines, without the least deviation. But if it happens to pass from one medium to another, it always leaves the direction it had before, and assumes a new one; and this change of course is called its *refraction*. After having taken this new direction, it then proceeds invariably in a straight line till it meets with a different medium, when it is again turned out of its course. It must be observed, however, that tho' by this means we may cause the rays of light make any number of angles in their course, it is impossible for us to make them describe a curve, except in one single case, namely, where they pass through a medium, the density of which uniformly either increases or decreases. This is the case with the light of the celestial bodies, which passes downwards thro' our atmosphere, and likewise with that which is reflected upwards through it by terrestrial objects. In both these cases, it describes a curve of the hyperbolic kind; but at all other times it proceeds in straight lines, or in what may be taken for straight lines without any sensible error. 112

112 In what case the rays of light describe a curve.

Of Refraction.

§ 1. *The cause of Refraction, and the law by which it is performed.*

113 Phenomena of refraction solved by an attractive power in the medium.

The phenomena of refraction are explained by an attractive power in the medium through which light passes, in the following manner. All bodies being endowed with an attractive force, which is extended to some distance beyond their surfaces; when a ray of light passes out of a rarer into a denser medium (if this latter has a greater attractive force than the former, as is commonly the case) the ray, just before its entrance, will begin to be attracted towards the denser medium; and this attraction will continue to act upon it, till some time after it has entered the medium; and therefore, if a ray approaches a denser medium in a direction perpendicular to its surface, its velocity will be continually accelerated during its passage through the space in which that attraction exerts itself; and therefore, after it has passed that space, it will move on, till it arrives at the opposite side of the medium, with a greater degree of velocity than it had before it entered. So that in this case its velocity only will be altered. Whereas, if a ray enters a denser medium obliquely, it will not only have its velocity augmented thereby, but its direction will become less oblique to the surface. Just as when a stone is thrown downwards obliquely from a precipice, it falls to the surface of the ground in a direction nearer to a perpendicular one, than that with which it was thrown from the hand. From hence we see a ray of light, in passing out of a rarer into a denser medium, is refracted towards the perpendicular; that is, supposing a line drawn perpendicularly to the surface of the medium, through the point where the ray enters, and extended both ways, the ray in passing through the surface is refracted or bent towards the perpendicular line; or, which is the same thing, the line which it describes by its motion after it has passed through the surface, makes a less angle with the perpendicular, than the line it described before. All which may be illustrated in the following manner.

Let us suppose first, that the ray passes out of a vacuum into the denser medium ABCD, (fig. 4.) and that the attractive force of each particle in the medium is extended from its respective centre to a distance equal to that which is between the lines AB and EF, or AB and GH; and let KL be the path described by a ray of light in its progress towards the denser me-

Plate CCVIII.

medium. This ray, when it arrives at L, will enter the attractive forces of thofe particles which lie in AB the furface of the denfer medium, and will therefore ceafe to proceed any longer in the right line KLM, but will be diverted from its courfe by being attracted towards the line AB, and will begin to defcribe the curve LN, paffing thro' the furface AB in fome new direction, as OQ; thereby making a lefs angle with a line, as PR, drawn perpendicularly through the point N, than it would have done had it proceeded in its firft direction KLM.

Farther, whereas we have fuppofed the attractive force of each particle to be extended through a fpace equal to the diftance between AB and EF, it is evident, that the ray, after it has entered the furface, will ftill be attracted downwards, till it has arrived at the line EF; for, till that time, there will not be fo many particles above it which will attract it upwards, as below, that will attract it downwards. So that after it has entered the furface at N, in the direction OQ, it will not proceed in that direction, but will continue to defcribe a curve, as NS; after which it will proceed ftraight on towards the oppofite fide of the medium, being attracted equally every way; and therefore will at laft proceed in the direction XST, ftill nearer the perpendicular PR than before.

Now if we fuppofe ABYZ not to be a vacuum, but a rarer medium than the other, the cafe will ftill be the fame; but the ray will not be fo much refracted from its rectilineal courfe, becaufe the attraction of the particles of the upper medium being in a contrary direction to that of the attraction of thofe in the lower one, the attraction of the denfer medium will in fome meafure be deftroyed by that of the rarer.

On the contrary, when a ray paffes out of a denfer into a rarer medium, if its direction be perpendicular to the furface of the medium, it will only lofe fomewhat of its velocity, in paffing through the fpaces of attraction of that medium (that is, the fpace wherein it is attracted more one way than it is another.) If its direction be oblique, it will continually recede from the perpendicular during its paffage, and by that means have its obliquity increafed, juft as a ftone thrown up obliquely from the furface of the earth increafes its obliquity all the time it rifes. Thus, fuppofing the ray TS paffing out of the denfer medium ABCD into the rarer ABYZ, when it arrives at S it will begin to be attracted downwards, and fo will defcribe the curve SNL, and then proceed in the right line LK; making a larger angle with the perpendicular PR, than the line TSX in which it proceeded during its paffage through the other medium.

The fpace through which the attraction of cohefion of the particles of matter is extended is fo very fmall, that in confidering the progrefs of a ray of light out of one medium into another, the curvature it defcribes in paffing through the fpace of attraction is generally neglected; and its path is fuppofed to be bent, or, in the ufual terms, the ray is fuppofed to be refracted only in the point where it enters the denfer medium.

Now the line which a ray defcribes before it enters a denfer or a rarer medium, is called the *incident ray;* that which it defcribes after it has entered, is the *refracted ray.*

The angle comprehended between the incident ray and the perpendicular, is the *angle of incidence;* and that between the refracted ray and the perpendicular, is the *angle of refraction.*

There is a certain and immutable law or rule, by which refraction is always performed; and that is this: Whatever inclination a ray of light has to the furface of any medium before it enters it, the degree of refraction will always be fuch, that the proportion between the fine of the angle of its incidence, and that of the angle of its refraction, will always be the fame in that medium.

To illuftrate this: Let us fuppofe ABCD (fig. 5.) to reprefent a rarer, and ABEF a denfer medium: let GH be a ray of light paffing through the firft and entering the fecond at H, and let HI be the refracted ray: then fuppofing the perpendicular PR drawn thro' the point H, on the centre H, and with any radius, defcribe the circle APBR; and from G and I, where the incident and refracted rays cut the circle, let fall the lines GK and IL perpendicularly upon the line PR; the former of thefe will be the fine of the angle of incidence, the latter of refraction. Now if in this cafe the ray GH is fo refracted at H, that GK is double or triple, &c. of IL, then, whatever other inclination the ray GH might have had, the fine of its angle of incidence would have been double or triple, &c. to that of its angle of refraction. For inftance, had the ray paffed in the line MH before refraction, it would have paffed in fome line as HN afterwards, fo fituated that MO fhould have been double or triple &c. of NQ. Plate CCVIII.

When a ray paffes out of a vacuum into air, the fine of the angle of incidence is found to be to that of refraction, as 100036 to 100000.

When it paffes out of air into water, as about 4 to 3.

When out of air into glafs, as about 17 to 11.

When out of air into a diamond, as about 5 to 2.

This relation of the fine of the angle of incidence to that of refraction may be demonftrated mathematically in the following manner.

Lemma. If from a point at M (fig. 6.) taken any where without the circle PNQ, a line as MP be drawn paffing through L the centre of the circle, and terminated in the circumference at P, the product of MQ multiplied by MP is equal to the difference between the fquares of ML and PL.

Demonftration of the Lemma. Call MQ, a; and the radius of the circle LQ or LP, b; then will the diameter QP be expreffible by $2b$, and the whole line MP, by $a+2b$; then multiplying MQ by MP, that is, a by $a+2b$, we have for the product of this, $aa+2ab$. Now the fquare of the line ML, which is expreffible by $a+b$, is $aa+2ab+bb$; and the fquare of PL is bb; but the difference between thefe fquares, *viz.* $aa+2ab+bb$ and bb, is evidently $aa+2ab$; and therefore the product of MQ multiplied by MP is equal to the difference between the fquares of ML and PL. *Q. E. D.*

Demonftration of the Propofition. When a ray of light paffes through the fpace of attraction of any medium, it is evident that its motion will be fubject to the like laws with that of projectiles, provided we fuppofe it to be acted upon with an equal degree of force during its whole paffage through that fpace, as is commonly fuppofed to be the cafe in projectiles to whatever

Of Refraction.

ever height they are thrown from the earth. We will therefore suppose first, that the force of attraction of the denser medium is at all distances the same as far as it reaches, and that the ray proceeds out of a denser into a rarer medium; in which case it will be attracted back towards the denser medium, during its passage thro' the space of attraction, in like manner as a projectile thrown upwards is while it rises from the earth. Let then ABCD (fig. 6.) represent the denser medium, and ABEF the space of attraction; and let GH be a ray about to enter the force of attraction at H, and let GH be produced to M. Now it is evident, that, in this supposition, the ray, when at H, is in the same circumstances with a projectile about to be thrown upwards from H towards M: it will therefore describe a portion of a parabola as HI; to which the line HM will be a tangent at H; and the line IK, in which it would proceed after it had passed the space of attraction, a tangent to it at I; for after having left the attractive force at I, it goes straight on in its last direction. Let the perpendicular IR be drawn meeting GH produced in M, and let KI be produced to L. On the centre L, with the radius LI, describe the circle PNQ, let fall the perpendicular LO upon MR, and join the points L and N. Now it is demonstrated in the case of projectiles†, that the parameter of the point H is equal to $\frac{HMq}{MI}$, and therefore the parameter multiplied by MI is equal to HM*q*. And it is there farther demonstrated, that the said parameter is equal to four times the height which a body must fall from, to acquire the velocity the projectile has at H. This parameter therefore is a quantity not at all depending on the direction of the projectile, but on its velocity only; and consequently, in the present supposition, it is a given quantity, the ray GH being sudposed to have the same velocity, whatever is its inclination to the surface HB. Now the tangent KI being produced to L, will, by the property of the parabola, bisect the other tangent HM: wherefore the line LO being parallel to HR, MR will also be bisected in O; and adding the equal lines OI and ON to each part, MN will be equal to IR; but the line IR is also a line independent of the inclination of the ray GH, its length being determined by the breadth of the space of attraction ABEF only, and therefore MN is a given quantity. Now, whereas MI, when multiplied by the parameter of the point H, which before was shewn to be a given line, is equal to the square of HM, therefore the same line MI, when multiplied by any other given line (*viz.* MN) if it is not equal to, will nevertheless bear a given proportion to, the square of HM: but since MI multiplied by MN bears a given proportion (*viz.* a proportion that does not depend on the inclination of the ray GH) to the square of MH, its equal, *viz.* the product of MQ multiplied by MP, or what is equal to this, the difference between the squares of ML and PL (by the foregoing *lemma*), or, which is the same thing, of ML and LI, (because PL and LI are radii of the same circle), does so too. Now the square of ML bears also a given proportion to the square of MH (ML being equal to half MH); consequently there is a given proportion between the square of ML and the difference of the squares of ML and LI; and therefore there is a certain proportion between the lines themselves, *viz.* between ML and LI. But in every triangle the sides are proportionable to the sines of their opposite angles; therefore in the triangle MLI, the sine of the angle LMI has a given proportion to the sine of the angle LIM, or of its complement to two right ones MIK (for they have the same sine): But LMI, being an angle made by the incident ray GH produced, with the perpendicular RM, is the angle of incidence; and MIK, being made by the refracted ray IK, and the same perpendicular, is the angle of refraction; therefore in this case there is a constant ratio between the sine of the angle of incidence, and that of the angle of refraction.

Plate CCVIII.

† See the article *Projectiles*.

We have here supposed that the force of attraction is every where uniform; but if it be otherwise, provided it be the same every where at the same distances from the surface AB, the proportion between the forementioned sines will still be a given one. For, let us imagine the space of attraction divided into parallel planes, and the attraction to be the same through the whole breadth of each plane though different in different planes, the sine of the angle of incidence out of each will, by what has been demonstrated above, be to the sine of the angle of refraction into the next in a given ratio; and therefore, since the sine of the angle of refraction out of one will be the sine of the angle of incidence into the next, it is evident that the sine of the angle of incidence into the first will be in a given ratio to the sine of the angle of refraction out of the last. Now let us suppose the thickness of these planes diminished *in infinitum*, and their number proportionably increased, the law of refraction will still continue the same; and therefore, whether the attraction be uniform or not, there will be a constant ratio between the sine of the angle of incidence and of refraction. *Q. E. D.*

For the same reason that a ray is bent towards the perpendicular when passing from a rare medium into one that is denser, it is refracted from the perpendicular when it passes from a dense medium into one that is rarer—From this and the foregoing proposition may be deduced the following corollaries.

I. When parallel rays fall obliquely on a plane surface of a medium of different density, they are parallel also after refraction; for, having all the same inclination to the surface, they suffer an equal degree of refraction.

II. When diverging rays pass out of a rarer into a denser medium through a plain surface, they are made thereby to diverge less.

III. When they proceed out of a denser into a rarer medium, the contrary happens, and they diverge more.

IV. When converging rays pass out of a rarer into a denser medium through a plain surface, they are made thereby to converge less.

V. When converging rays proceed out of a denser into a rarer medium, they are refracted the contrary way, and so made to converge more.

All these may be illustrated in the following manner. 1. Let AB, CD (fig. 7.) be two parallel rays falling on the plain surface EF of a medium of different density: now because they both make equal angles of incidence with their respective perpendicular GH, IK, before refraction, they will make equal angles of refrac-

refraction with them afterwards, and so proceed on in the parallel lines BL, DM. 2. Let the diverging rays AB, AE, AF, (fig. 8.) pass out of a rarer into a denser medium through the plain surface GH, and let the ray AB be perpendicular to that surface; the rest being refracted towards their respective perpendiculars EK, FM, and those the most that fall the farthest from B, they will proceed in the directions EN and FO, diverging in a less degree from the ray AP than they did before refraction. 3. Had they proceeded out of a denser into a rarer medium, they would have been refracted from their perpendicular EK, FM; and those the most which were the most oblique, and therefore would have diverged more than before. 4. Let the converging rays AB, CD, EF (fig. 9.) pass out of a rarer into a denser medium through the plain surface GH, and let the ray AB be perpendicular to that surface; then the other rays being refracted towards their respective perpendiculars DK, FM; and EF, for instance, more than CD; they will proceed in the directions DN, FN, converging in a less degree towards the ray AN, than they did before. 5. Lastly, had the first medium been the denser, they would have refracted the other way, and therefore converged more.

VI. When rays proceed out of a rarer into a denser medium through a convex surface of the denser, if they are parallel before refraction, they become converging afterwards.—For in this case the perpendiculars at the points where the rays enter the surface are all drawn from the centre of the convexity on the other side; and therefore, as the rays are refracted towards these perpendiculars, they are necessarily refracted towards each other, and thereby made to converge.

VII. If they enter diverging, then for the same reason they are made to diverge less, to be parallel, or to converge, according to the degree of divergency they have before they enter.

For, if they diverge very much, their being bent towards their respective perpendiculars in passing thro' the surface, may only diminish the divergency; whereas, if they diverge in a small degree, it may make them parallel, or even to converge.

VIII. If they converge in such a manner as to tend directly towards the centre of convexity before they enter the surface, they fall in with their respective perpendiculars, and so pass on to the centre without suffering any refraction.

IX. If they converge less than their perpendiculars, that is, if they tend to a point beyond the centre of convexity, they are made by refraction to converge more; and if they converge more than their perpendiculars, that is, if they tend towards a point between the centre and the surface, then, by being refracted towards them, they are made to converge less.

This and the three foregoing corollaries may be illustrated in the following manner. 1. Let AB, CD (fig. 10.) be two parallel rays entering a denser medium through the convex surface DB, whose centre of convexity is E; and let one of these, viz. AB, be perpendicular to the surface. This will pass on through the centre, without suffering any refraction; but the other being oblique to the surface, will be refracted towards the perpendicular ED, and will therefore be made to proceed in some line, as DG, converging towards the other ray, and meeting it in G, which point for that reason is called the *focus*. 2. Had the ray CD diverged from the other, suppose in the line AD, it would, by being refracted towards its perpendicular ED, have been made either to diverge less, be parallel, or made to converge. 3. Let the line ED be produced to F, and if the ray had converged, so as to have described the line FD, it would have been coincident with its perpendicular, and have suffered no refraction at all. 4. If it had proceeded from any point between C and F, as from H, or, which is the same thing, towards any point beyond E in the line BE produced, it would have been made to converge more by being refracted towards the perpendicular DE, which converges more than it; and, had it proceeded from the same point, as I, on the other side of F, that is towards any point between B and E, it would then have converged more than its perpendicular, and so, being refracted towards it, would have been made to have converged less.

X. When rays proceed out of a denser into a rarer medium through a concave surface of the denser, the contrary happens in each case.

For, being now refracted from their respective perpendiculars, as they were before towards them, if they are parallel before refraction, they diverge afterwards; if they diverge, their divergency is increased; if they converge in the direction of their perpendiculars, they suffer no refraction; if they converge less than their respective perpendiculars, they are made to converge still less, to be parallel, or to diverge; if they converge more, their convergency is increased. All which may be clearly seen by the figure, without any further illustration; imagining the rays AD, CD, &c. bent the contrary way in their refractions to what they were in the former cases.

XI. When rays proceed out of a rarer into a denser medium through a concave surface of the denser, if they are parallel before refraction, they are made to diverge.—For in this case the perpendiculars at the points where the rays enter the surface, being drawn from a point on that side of the surface from which the rays tend; if we conceive them to pass through the surface, they will be so many diverging lines on the other side; and therefore the rays, after they have passed through the same points, must necessarily be rendered diverging in being refracted towards them.

XII. If they diverge before refraction, then, for the same reason, they are made to diverge more.

XIII. Unless they proceed directly from the centre; in which case they fall in with their perpendiculars, and suffer no refraction: Or from some point between the centre of convexity and the surface; for then they diverge more than their respective perpendiculars, and therefore being by refraction brought towards them they become less diverging.

XIV. If they converge, then, being refracted towards their perpendiculars, they are either made less converging, parallel, or diverging, according to the degree they converged in before refraction.

To illustrate this, and the three foregoing cases, 1. Let AB, CD (fig. 11.), be two parallel rays entering the concave and denser medium X, the centre of whose convexity is E, and the perpendicular to the refracting

refracting surface at the point D is EF: the ray AB, if we suppose it perpendicular to the surface at B, will proceed on directly to G; but the oblique one CD being refracted towards the perpendicular DF, will recede from the other ray AG in some line as DH. 2. If the ray CD had proceeded from A, diverging in the direction AD, it would have been bent nearer the perpendicular, and therefore have diverged more. 3. But if it had diverged from the centre E, it would have fallen in with the perpendicular EF, and not have been refracted at all: and had it proceeded from S, a point on the other side of the centre E, it would, by being refracted towards the perpendicular DF, have proceeded in some line nearer it than it would otherwise have done, and so would diverge less than before refraction. 4. If it had converged in the line LD, it would have been rendered less converging, parallel, or diverging, according to the degree of convergency which it had before it entered into the refracting surface.

XV. If the same rays proceed out of a denser into a rarer medium, through a convex surface of the denser, the contrary happens in each supposition. The parallels are made to converge; those which diverge less than their respective perpendiculars, that is, those which proceed from a point beyond the centre, are made less diverging, parallel, or converging, according to the degree in which they diverge before refraction; those which diverge more than their respective perpendiculars, that is, those which proceed from a point between the centre and the refracting surface, are made to diverge still more; and those which converge are made to converge more. All which may easily be seen by considering the situation of the rays AB, CD, &c. with respect to the perpendicular EF; and therefore requires no further illustration.

XVI. When diverging rays are by refraction made to converge, the nearer the radiant point (or point whence the rays proceed) is to the refracting surface, the farther is their focus from it on the other side, and *vice versa*. For the nearer the radiant point is to the refracting surface, the more the rays which fall upon the same points of it diverge before refraction, upon which account they converge the less afterwards.

XVII. When the radiant point is at that distance from the surface at which parallel rays coming through it from the other side would be collected by refraction, then rays flowing from that point become parallel on the other side, and are said to have their focus at an infinite distance. For the power of refraction in the medium is the same, whether the ray passes one way or other. For instance, if the parallel rays AB, CD, (fig. 10.) in passing through the refracting surface BD, are brought to a focus in G, then rays flowing from G as a radiant point, will afterwards proceed in the parallel lines BA and DC. And the point G, where the parallel rays AB and CD meet after refraction, is called the *focus of parallel rays*.

XVIII. When rays proceed from a point nearer the refracting surface than the focus of parallel rays, they continue to diverge after refraction, and their focus is then an imaginary one, and situated on the same side of the surface with the radiant. For, in this case, the divergency being greater than that which they would have if they had proceeded from the focus of parallel rays, they cannot be brought to a parallelism with one another, much less to converge; and therefore they continue to diverge, though in a less degree than before they passed through the refracting surface: upon which account they proceed after refraction as if they came from some point farther distant from the refracting surface than their radiant.

All these corollaries may be expressed more determinately, and demonstrated, in the following manner:

I. When rays pass out of one medium into another of different density through a plain surface; if they diverge, the focal distance will be to that of the radiant point; if they converge, it will be to that of the imaginary focus of the incident rays, as the sine of the angle of incidence is to that of the angle of refraction.

This proposition admits of four cases.

Case 1. Of diverging rays passing out of a rarer into a denser medium.

Dem. Let X (fig. 12.) represent a rarer, and Z a denser medium, separated from each other by the plane surface AB; suppose CE and CD to be two diverging rays proceeding from the point C, the one perpendicular to the surface, the other oblique; through E draw the perpendicular PK. The ray CD being perpendicular to the surface, will proceed on in the right line CQ; but the other falling on it obliquely at E, and there entering a denser medium, will suffer a refraction towards the perpendicular EK. Let then EG be the refracted ray, and produce it back till it intersects DC produced also in F; this will be the focal point. On the centre E, and with the radius EF, describe the circle AFBQ, and produce EC to H; draw HI the sine of the angle of incidence, and GK that of refraction; equal to this is FP or CM, which let be drawn. Now if we suppose the points D and E contiguous, or nearly so, then will the line HE be almost coincident with FD, and therefore FD will be to CD as HE to CE; but HE is to CE as HI to CM, because the triangles HIE and CME are similar; that is, the focal distance of the ray CE is to the distance of the radiant point, as the sine of the angle of incidence is to that of the angle of refraction. *Q. E. D.*

Obs. 1. Whereas the ratio of FE to ME, or, which is the same thing, that of nD to CD, bears the exact proportion of HI to CM, and because this (being the ratio of the sine of the angle of incidence to that of the angle of refraction) is always the same, the line In is in all inclinations of the ray CE, at the same distance from CM; consequently, had CE been coincident with CD, the point H had fallen upon n; and because the circle passes through both H and F, F would also have fallen upon n; upon which account the focus of the ray CE would have been there. But the ray CE being oblique to the surface DB, the point H is at some distance from n; and therefore the point F is necessarily so too, and the more so by how much the greater that distance is: from whence it is clear, that no two rays flowing from the radiant point C, and falling with different obliquities on the surface BD, will, after refraction there, proceed as from the same point; therefore, strictly speaking, there is no one

Of Refraction.

one point in the line D produced, that can more properly be called the *focus of rays flowing from* C, than another: for thofe which enter the refracting furface near D, will after refraction proceed, as has been obferved, from the parts abont *n;* thofe which enter near E, will flow as from the parts about F; thofe which enter about T, as from fome points in the line DF produced, &c. And it is farther to be obferved, that, when the angle DCE becomes large, the line *n*F increafes apace; wherefore thofe rays which fall near T, proceed, after refraction, as from a more diffufed fpace than thofe which fall at the fame diftance from each other near the point D. Upon which account it is ufual with optical writers to fuppofe the diftance between the points where the rays enter the plain furface of a refracting medium, to be inconfiderable with regard to the diftance of the radiant point, if they diverge; or to that of their imaginary focus, if they converge: and unlefs there be fome particular reafon to the contrary, they confider them as entering the refracting medium in a direction as nearly perpendicular to its furfaces as may be.

Case 2. Of diverging rays proceeding out of a denfer into a rarer medium.

Dem. Let X be the denfer, Z the rarer medium, FD and FE two diverging rays proceeding from the point F; and fuppofing the perpendicular PK drawn as before, FP will be the fine of the angle of incidence of the oblique ray FE; which in this cafe being refracted from the perpendicular, will pafs on in fome line as ER, which being produced back to the circumference of the circle, will cut the ray FD fomewhere, fuppofe in C; this therefore will be the imaginary focus of the refracted ray ER: draw RS the fine of the angle of refraction, to which HI will be equal: but here alfo FP, or its equal CM, is to HI as EC to EH, or (if the point D and E be confidered as contiguous) as DC to DF; that is, the fine of the angle of incidence is to the fine of the angle of refraction, as the focal diftance to that of the radiant point. *Q. E. D.*

Case 3. Of converging rays paffing out of a denfer medium into a rarer.

Dem. Let Z be the denfer, X the rarer medium, and GE the incident ray; this will be refracted from the perpendicular into a line, as EH; then all things remaining as before, GK, or its equal FP, or CM, will be the fine of the angle of incidence, and HI that of refraction: but thefe lines, as before, are to each other as DC to DF; that is, the focal diftance is to the diftance of the imaginary focus, as the fine of the angle of incidence to that of the angle of refraction. *Q. E. D.*

Case 4. Of converging rays paffing out of a rarer into a denfer medium.

Dem. Let Z be the rarer, X the denfer medium, and RE the incident ray; this will be refracted towards the perpendicular into a line, as EF; C will be the imaginary focus, and F the real one; HI, which is equal to RS, the fine of the angle of incidence, and FP that of the angle of refraction: but thefe are to each other, as DF to DC; and therefore the focal diftance is to that of the imaginary focus, as the fine of the angle of incidence is to that of the angle of refraction. *Q. E. D.*

II. When parallel rays fall upon a fpherical furface of different denfity, the focal diftance will be to the diftance of the centre of convexity, as the fine of the angle of incidence is to the difference between that fine and the fine of the angle of refraction.

This propofition admits of four cafes.

Case 1. Of parallel rays paffing out of a rarer into a denfer medium, through a convex furface of the denfer.

Plate CCVII.

Dem. Let AB (fig. 13.) reprefent a convex furface; C its centre of convexity; HA and DB two parallel rays, paffing out of the rarer medium X into the denfer Z, the one perpendicular to the refracting furface, the other oblique: draw CB; this being a radius, will be perpendicular to the furface at the point B; and the oblique ray DB, being in this cafe refracted towards the perpendicular, will proceed in fome line, as BF, meeting the other ray in F, which will therefore be the focal point: produce CB to N; then will DBN, or its equal BCA, be the angle of incidence, and FBC that of refraction. Now, whereas any angle has the fame fine with its complement to two right ones, the angle FCB being the complement of ACB, which is equal to the angle of incidence, may here be taken for that angle; and therefore, as the fides of a triangle have the fame relation to each other that the fines of their oppofite angles have, FB being oppofite to this angle, and FC being oppofite to the angle of refraction, they may here be confidered as the fines of the angles of incidence and of refraction. And for the fame reafon CB may be confidered as the fine of the angle CFB; which angle being, together with the angle FBC, equal to the external one ACB, (32. El. 1.) is itfelf equal to the difference between thofe two laft angles; and therefore the line FB is to CB as the fine of the angle of incidence is to the fine of an angle which is equal to the difference between the angle of incidence and of refraction. Now, becaufe in very fmall angles as thefe are, (for we fuppofe in this cafe alfo the diftance AB to vanifh, the reafon of which will be fhewn by-and-by,) their fines bear nearly the fame proportion to each other that they themfelves do, the diftance FB will be to CB as the fine of the angle of incidence is to the difference between that fine and the fine of the angle of refraction; but becaufe BA vanifhes, FB and FA are equal, and therefore FA is to CA in that proportion. *Q. E. D.*

Obs. 2. It appears from the foregoing demonftration, that the focal diftance of the oblique ray DB is fuch, that the line BF fhall be to the line CB or CA as the fine of the angle of incidence to the fine of an angle, which angle is equal to the difference between the angle of incidence and refraction; therefore, fo long as the angles BCA, &c. are fmall, fo long the line BF is pretty much of the fame length, becaufe fmall angles have nearly the fame relation to each other that their fines have. But when the point B is removed far from A, fo that the ray DB enters the furface, fuppofe about O, the angles BCA, &c. becoming large, the fine of the angle of incidence begins to bear a confiderably lefs proportion to the fine of an angle which is equal to the difference between the angle of incidence and refraction than before, and therefore the line BF begins to bear a much lefs proportion to BC; wherefore its length decreafes apace: upon which account thofe rays which enter the furface about

Of Refraction.

about O, not only meet nearer the centre of convexity than thofe which enter at A, but are collected into a more diffufed fpace. From hence it is, that the point where thofe only which enter near A are collected, is reckoned the true focus; and the diftance AB in all demonftrations relating to the foci of parallel rays entering a fpherical furface whether convex or concave, is fuppofed to vanifh.

Case 2. Of parallel rays paffing out of a denfer into a rarer medium through a concave furface of the denfer.

Dem. Let X be the denfer, Z the rarer medium. AB the furface by which they are feparated, C the centre of convexity, and HA and DB two parallel rays, as before. Through B, the point where the oblique ray DB enters the rarer medium, draw the perpendicular CN; and let the ray DB, being in this cafe refracted from the perpendicular, proceed in the direction BM; produce BM back to H; this will be the imaginary focus; and DBN, or its equal ACB, will be the angle of incidence, and CBM, or its equal HBN (for they are vertical) that of refraction: produce DB to L, and draw BF fuch, that the angle LBF may be equal to DBH: then becaufe NBD and DBH together are equal to NBH the angle of refraction, therefore BCA which is equal to the firft, and LBF which is equal to the fecond, are together equal to the angle of refraction; but LBF is equal to BFA (as being alternate to it); confequently BFA and BCA together are equal to the angle of refraction; and therefore fince one of them, *viz.* BCA, is equal to the angle of incidence, the other is the difference between that angle and the angle of refraction. Now FB, the fine of the angle FCB, or, which is the fame thing, of its complement to two right ones, BCA, the angle of incidence, is to CB the fine of the angle BFC, as FB to CB, that is, as HB to CB; for the angles DBH and LBF being equal, the lines BF and BH are fo too; but the diftance BA vanifhing, HB is to CB, as HA to CA: that is, the fine of the angle of incidence is to the fine of an angle which is the difference between the angle of incidence and refraction, or, becaufe the angles are fmall, to the difference between the fine of the angle of incidence and that of refraction, as the diftance of the focus from the furface is to that of the centre from the fame. *Q. E. D.*

Case 3. Of parallel rays paffing out of a rarer into a denfer medium through a concave furface.

Dem. Let X be the denfer medium having the concave furface AB, and let LB and FA be the incident rays. Now, whereas, when DB was the incident ray, and paffed out of a rarer into a denfer medium, as in Cafe 1. it was refracted into the line BF, this ray LB, having the fame inclination to the perpendicular, will alfo fuffer the fame degree of refraction, and will therefore pafs on afterwards in the line FB produced, *v. g.* towards P. So that, whereas in that cafe the point F was the real focus of the incident ray DB, the fame point will in this be the imaginary focus of the incident ray LB: but it was there demonftrated, that the diftance FA is to CA, as the fine of the angle of incidence is to the difference between that and the fine of the angle of refraction; therefore the focal diftance of the refracted ray BP is to the diftance of the centre of convexity in that proportion. *Q. E. D.*

Case 4. Of parallel rays paffing out of a denfer into a rarer medium through a convex furface of the denfer.

Dem. Let Z be the denfer medium, having the convex furface AB, and let LB and FA be the incident rays, as before. Now, whereas, when DB was the incident ray paffing out of a denfer into a rarer medium, it was refracted into BM, as in Cafe 2. having a point as H in the line MB produced for its imaginary focus; therefore LB, for the like reafon as was given in the laft cafe, will in this be refracted into BH, having the fame point H for its real focus. So that here alfo the focal diftance will be to that of the centre of convexity, as the fine of the angle of incidence is to the difference between that and the fine of the angle of refraction. *Q. E. D.*

III. When diverging or converging rays enter into a medium of different denfity through a fpherical furface, the ratio compounded of that which the focal diftance bears to the diftance of the radiant point (or of the imaginary focus of the incident rays, if they converge), and of that which the diftance between the fame radiant point (or imaginary focus) and the centre bears to the diftance between the centre and focus, is equal to the ratio which the fine of the angle of incidence bears to the fine of the angle of refraction.

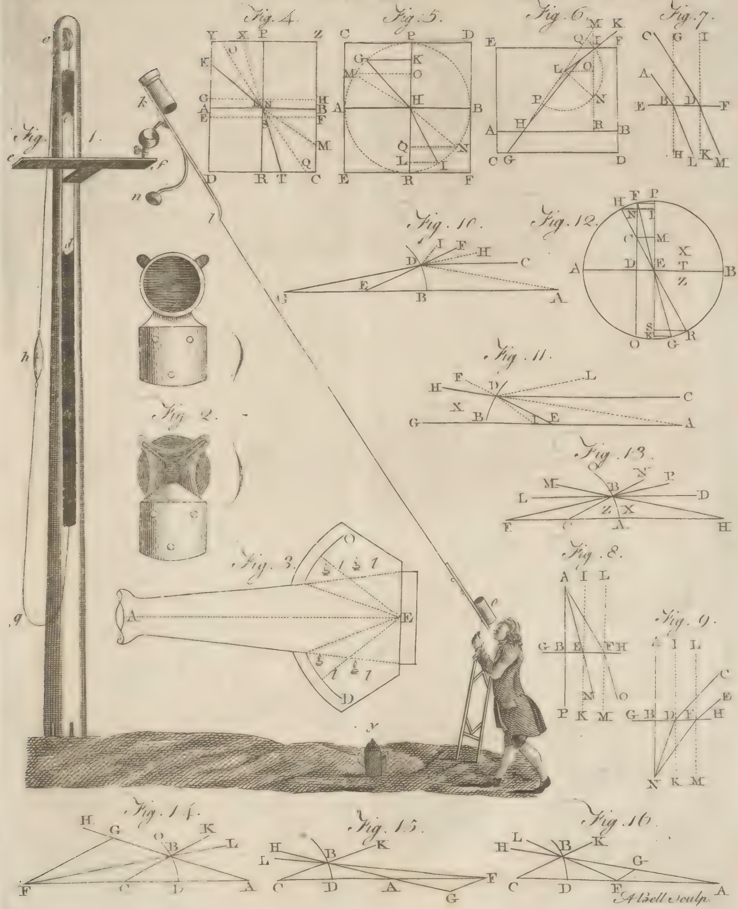
This propofition admits of 16 cafes.

Case 1. Of diverging rays paffing out of a rarer into a denfer medium, thro' a convex furface of the denfer, with fuch a degree of divergency, that they fhall converge after refraction.

Plate CCVIII.

Dem. Let BD (fig. 14.) reprefent a fpherical furface, C its centre of convexity; and let there be two diverging rays AB and AD proceeding from the radiant point A, the one perpendicular to the furface, the other oblique. Thro' the centre C produce the perpendicular one to F; and draw the radius CB, and produce it to K, and let BF be the refracted ray; then will F be the focal point; produce AB to H, and through the point F draw the line FG parallel to CB. AB being the incident ray, and CK perpendicular to the furface at the point B, the angle ABK, or, which is equal to it, becaufe of the parallel lines CB and FG, FGH, is the angle of incidence. Now, whereas, the complement of any angle to two right ones has the fame fine with the angle itfelf, the fine of the angle FGB, that being the complement of FGH to two right ones, may be confidered as the fine of the angle of incidence; which fine the line FB, as the fides of a triangle have the fame relation to each each other that the fines of their oppofite angles have, may be taken for. Again, the angle FBC is the angle of refraction, or its equal, becaufe alternate to it, BFG; to which BG, being an oppofite fide, may be looked upon as the fine. But FB is to BG in a ratio compounded of FB to BA, and of BA to BG; for the ratio that any two quantities bear to each other, is compounded of the ratio which the firft bears to any other, and of the ratio which that other bears to the fecond. Now FB is to BA, fuppofing BD to vanifh, as FD to DA; and BA is to BG, becaufe of the parallel lines CB and FG, as AC to CF. That is, the ratio

OPTICS. Plate CCVIII.



Of Refraction.

ratio compounded of FD the focal diſtance, to DA the diſtance of the radiant point, and of AC, the diſtance between the radiant point and the centre, to CF, the diſtance between the centre and the focus, is equal to that which the fine of the angle of incidence bears to the fine of the angle of refraction. *Q. E. D.*

Plate CCVIII. fig. 14.

Obs. Whereas the focal diſtance of the oblique ray AB is ſuch, that the compound ratio of FB to BA and of AC to CF, ſhall be the ſame, whatever be the diſtance between B and D; it is evident, that ſince AC is always of the ſame length, the more the line AB lengthens, the more FB muſt lengthen too, or elſe FC muſt ſhorten: but it appears by inſpection of the figure, that if BF lengthens, CF will do ſo too, and in a greater proportion with reſpect to its own length than BF will; therefore the lengthening of BF will conduce nothing towards preſerving the equality of the proportion; but as AB lengthens, BF and CF muſt both ſhorten, which is the only poſſible way wherein the proportion may be continued the ſame. And it is alſo apparent, that the farther B moves from D towards O, the faſter AB lengthens; and therefore the farther the rays enter from D, the nearer to the refracting ſurface is the place where they meet, but the ſpace they are collected in is the more diffuſed: and therefore, in this caſe, as well as thoſe taken notice of in the two foregoing obſervatſons, different rays, tho' flowing from the ſame point, ſhall conſtitute different focuſes; and none are ſo effectual as thoſe which enter at, or very near, the point D. And ſince the ſame is obſervable of converging as well as of diverging rays, none except thoſe which enter very near that point are uſually taken into conſideration; upon which account it is, that the diſtance DB, in determining the focal diſtances of diverging or converging rays entering a convex or concave ſurface, is ſuppoſed to vaniſh.

Thoſe who would ſee a method of determining the preciſe point, which the ray AB, whether it be parallel, converging, or diverging to the ray AF, converges to or diverges from after refraction at B or any other given point in the ſurface DO, may find it in the Appendix to Molineux's Optics; which, for the ſake of thoſe who have not the book, we ſhall ſubjoin at the end of this ſection.

Case 2. Of converging rays paſſing out of a rarer into a denſer medium through a concave ſurface of the denſer with ſuch a degree of convergency, that they ſhall diverge after refraction.

Dem. Let the incident rays be HB and FD paſſing out of a rarer into a denſer medium thro' the concave ſurface BD, and tending towards the point A, from whence the diverging rays flowed in the other caſe; then the oblique ray HB, having its angle of incidence HBC equal to ABK the angle of incidence in the former caſe, will be refracted into the line BL, ſuch, that its refracted angle KBL will be equal to FBC the angle of refraction in the former caſe; that is, it will proceed after refraction in the line FB produced, having the ſame focal diſtance FD with the diverging rays AB, AD, in the other caſe. But, by what has been already demonſtrated, the ratio compounded of FD, the focal diſtance, to DA, in this caſe, the diſtance of the imaginary focus of the incident rays, and of AC, the diſtance between the ſame imaginary focus and the centre, to CF, the diſtance between the centre and the focus, is equal to that which the fine of the angle of incidence bears to the fine of the angle of refraction. *Q. E. D.*

Case 3. Of diverging rays paſſing out of a rarer into a denſer medium through a convex ſurface of the denſer with ſuch a degree of divergency as to continue diverging.

Dem. Let AB, AD (fig. 15.) be the diverging rays, and let their divergency be ſo great, that the refracted ray BL ſhall alſo diverge from the other; produce LB back to F, which will be the focal point; draw the radius CB, and produce it to K; produce BA likewiſe towards G, and draw FG parallel to BC. Then will ABK be the angle of incidence, whoſe fine BF may be taken for, as being oppoſite to the angle BGF, which is the complement of the other to two right ones. And LBC is the angle of refraction, or its equal KBF, or, which is equal to this, BFG, as being alternate; therefore BG, the oppoſite ſide to this, may be taken for the fine of the angle of refraction. But BF is to BG, for the like reaſon as was given in caſe the firſt, in a ratio compounded of BF to BA, and of BA to BG. Now BF is to BA, (DB vaniſhing) as DF to DA; and becauſe of the parallel lines FG and BC, the triangles CBA and AGF are ſimilar; therefore BA is to AG as CA to AF; conſequently BA is to BA together with AG, that is, to BG, as CA is to CA together with AF, that is, CF. Therefore the ratio compounded of DF the focal diſtance to DA the diſtance of the radiant point, and of CA the diſtance between the radiant point and the centre, to CF the diſtance between the centre and the focus, is equal to that which the fine of the angle of incidence bears to the fine of the angle of refraction. *Q. E. D.*

Plate CCVIII.

Case 4. Of converging rays paſſing out of a rarer into a denſer medium thro' a concave ſurface of the denſer in ſuch manner that they ſhall continue converging.

Dem. Let HB and CD be the incident rays paſſing out of the rarer into the denſer medium thro' the concave ſurface BD, and tending towards A the ſame point from whence the diverging rays flowed in the laſt Caſe. Then becauſe the ray HB has the ſame inclination to the perpendicular CK that AB had before, it will ſuffer the ſame degree of refraction, and paſs on in the line LB produced, having its focus F at the ſame diſtance from the refracting ſurface as that of the diverging ray AB in the other caſe. Therefore, &c. *Q. E. D.*

Case 5. Of diverging rays paſſing out of a denſer into a rarer medium through a convex ſurface of the denſer.

Dem. Let AB, AD (fig. 16.) be the incident rays paſſing out of a denſer into a rarer medium through the concave ſurface BD whoſe centre is C; and let BL be the refracted ray, which produce back to F, and draw FG parallel to CB. Here ABK is the angle of incidence, to which its alternate one FGB being equal, FB the oppoſite ſide may be conſidered as the fine of it. The angle of refraction is LBC or FBK; of which BFG being the complement to two right ones, BG the oppoſite ſide may be looked upon as its fine. But BF is to BG, in the com-

Of Refraction.

compound ratio of BF to BA, and of BA to BG, for the reason given above. Now (BD vanishing) BF is to BA as DF to DA, and BA is to BG as CA to CF; that is, the ratio compounded of the focal distance to the distance of the radiant point, &c. *Q. E. D.*

Case 6. Of converging rays passing out of a denser into a rarer medium through a concave surface of the denser.

Dem. Let HB, CD, be the incident rays tending towards the point A which was the radiant in the last Case. Then, for the reason already given, the oblique ray will suffer such a degree of refraction, as to have its focus F at the same distance from the surface, as the diverging rays AB, AD, had in that case. Therefore, &c. *Q. E. D.*

When the mediums through which rays pass, and the refracting surfaces are such, that rays flowing from
Plate CCVIII.
A (fig. 14.) are collected in F, then rays flowing from F through the same mediums the contrary way, will be collected in A. For when rays pass out of one medium into another, the sine of the angle of incidence bears the same proportion to the sine of the angle of refraction, as the sine of the angle of refraction does to the sine of the angle of incidence, when they pass the contrary way. This is applicable to each of the six following Cases compared respectively with the six foregoing: therefore they may be considered as the converse of them; or they may be demonstrated independently of them, as follows.

Case 7. Of diverging rays passing out of a denser into a rarer medium through a concave surface of the denser, so as to converge afterwards.

Plate CCIX.
Dem. Let AB, AD (fig. 1.) be two diverging rays passing thro' the concave surface BD into a rarer medium. Let C be the centre of concavity, and BF the refracted ray. Draw CB, and produce it to K; and draw FG parallel to it, meeting AB produced in G. Then will ABC be the angle of incidence; of which FB being opposite to its alternate and equal angle FGB, may be considered as the sine. The angle of refraction is FBK; of which GB, being opposite to its complement to two right ones GFB, may be taken for the sine. Now FB is to BG in a ratio compounded of FB to BA, and of BA to BG. But (BD vanishing) FB is to BA as FD to DA; and because of the parallel lines CB and FG, BA is to BG as CA to CF. Therefore the focal distance, &c. *Q. E. D.*

Case 8. Of converging rays passing out of a denser into a rarer medium thro' a convex surface of the denser, so as to diverge afterwards.

Dem. Let GB and FD be the incident rays tending towards A, and produce FB to L. Then as AB in the last Case was refracted into BF, GB will in this be refracted into BL, for the reasons already given, having F for its focal point. Therefore, &c. *Q. E. D.*

Case. 9. Of diverging rays passing out of a denser into a rarer medium thro' a concave surface of the denser, in such a manner as to continue diverging.

Dem. Let AB, AD (fig. 2.) be two rays passing out of a denser into a rarer medium, through the concave surface DB, whose centre of concavity is C. Draw CB, produce it to K, and let BL be the refracted ray; produce BL back to F, and draw FG parallel to CB meeting BC produced in G. Then will ABC be the angle of incidence, of which FB being opposite to its alternative and equal angle FGB, may be considered as the sine. The refracted angle is LBK, or its equal CBF; of which BG, being opposite to its complement to two right ones BFG, is the sine. Now BF is to BG in the compound ratio of BF to BA and of BA to BG: but BF is to BA as DF to DA; and because of the parallel lines CB and FG, the triangles BCA, AGF, are similar: therefore BA is to AG as CA to AF, and consequently BA is to BG as CA to CF. Therefore, &c. *Q. E. D.*

Case 10. Of converging rays passing out of a denser into a rarer medium through a convex surface of the denser, in such manner as to continue converging.

Dem. Let HB, MD, be the incident rays tending towards the point A. Then will the oblique ray HB, for the reasons already given, be refracted in BF. Therefore, &c. *Q. E. D.*

Case 11. Of diverging rays passing out of a rarer into a denser medium through a concave surface of the denser.

Dem. Let AB, AD (fig. 3.) be the incident rays passing out of a rarer into a denser medium, through the concave surface BD, whose centre of convexity is C, and supposing the line CB drawn and produced to K, the refracted ray BL drawn and produced back to F, and also FG drawn parallel to CB, ABC will be the angle of incidence; of which FB, being opposite to its complement to two right ones BGF, is the sine. The angle of refraction will be LBK, or its equal FBC; of which BG, being opposite to its equal and alternate one BFG, is the sine. Now FB is to BG in the compound ratio of FB to BA and of BA to BG. But (BD vanishing) FB is to BA as FD to DA, and because of the parallel line FG and CB, BA is to BG as CA to CF. Therefore, &c. *Q. E. D.*

Case 12. Of converging rays passing out of a rarer into a denser medium through a convex surface of the denser.

Dem. Let HB, MD, be the incident rays tending towards A the radiant point in the last case; then, as was explained above, BF will be the refracted ray. Therefore, &c. *Q. E. D.*

Case 13. Of rays passing out of a rarer into a denser medium from a point between the centre of convexity and the surface.

Dem. Let AB, AD (fig. 4.) be two rays passing out of a rarer into a denser medium from the point A, which let be posited between C the centre of convexity and the refracting surface BD; through B draw CK, and let BL be the refracted ray; produce BL back to F, and draw FG parallel to BC. Then will ABC be the angle of incidence; of which BF, being opposite to its complement to two right ones BGF, is the sine. LBK will be the angle of refraction, or its equal FBC; of which BG, being opposite to its alternate and equal one BFG, is the sine. But, as before, BF is to BG in a compound ratio of BF to BA and of BA to BG; and (BD vanishing) BF is to BA as DF to DA, and because the lines CB and FG are pa-

Of Refraction. parallel, BA is to BG as CA to CF. Therefore, &c. *Q. E. D.*

CASE 14. Of rays paffing out of a denfer into a rarer medium towards a point between the centre of convexity and the furface.

DEM. Let the incident rays be MD, HB, tending towards A, from whence the other proceeded in the laft cafe. Then, as in that cafe the refracted ray BL being produced back paffed through F, in this the refracted ray itfelf, for the like reafons as were given in the foregoing cafes, will pafs through that point. Therefore, &c. *Q. E. D.*

CASE 15. Of rays paffing out of a rarer into a denfer medium from a point between the centre of convexity and the furface.

Plate CCIX. DEM. Let AB, AD (fig. 5.) be two diverging rays paffing out of a denfer into a rarer medium thro' the refracting furface BD, whofe centre of convexity is C, a point beyond that from whence the rays flow. Through B draw CK, and let BL be the refracted ray; produce it back to F, and draw FG parallel to BC, meeting BA produced in G. ABC will be the angle of incidence; of which BF, being oppofite to its alternate and equal angle BGF, is the fine. The angle of refraction is LBK, or its equal FBC; of which BG, being oppofite to its complement to two right ones BFG, is the fine. But BF is to BG in the compound ratio of BF to BA and of BA to BG; and (BD vanifhing) BF is to BA as DF to DA; and becaufe of the parallel lines CB and GF, the triangles AFG and ABC are fimilar. BA therefore is to AG, as CA to AF; confequently BA is to BA and AG together, that is, to BG, as CA is to CA and AF together, that is, to CF; and therefore the focal diftance, &c. *Q. E. D.*

CASE 16. Of rays paffing out of a denfer into a rarer medium towards a point between the centre of convexity and the furface.

DEM. Let HB, MD, be the incident rays having for their imaginary focus the point A, which was the radiant in the laft cafe; and let C the centre of convexity of the refracting furface be pofited beyond this point. Then will HB, for the reafons already given, be refracted into BF, having the point F for its real focus, which was the imaginary one of the diverging rays AB, AD, in the former cafe. Therefore, as before, the ratio compounded of that which the focal diftance bears to the diftance of the imaginary focus of the incident rays, and of that which the diftance between the fame imaginary focus and the centre bears to the diftance between the centre and the focus, is equal to the ratio which the fine of the angle of incidence bears to the fine of the angle of refraction. *Q. E. D.*

The firft term in the foregoing proportion (viz. that in propofition 3d) being always an unknown quantity, thofe who are not well verfed in the ufe of fuch propofitions, may think it impoffible to inveftigate the focal diftance of any refracting furface by it, we fhall therefore exemplify in the following inftance, by which the manner of doing it in all others will clearly be underftood. *V. g.* Let it be required to determine the focal diftance of diverging rays paffing out of air into glafs through a convex furface; and let the diftance of the radiant point be 20, and the radius of convexity be 5: now, becaufe we muft make ufe of the focal diftance before we know it, let that be expreffed by fome fymbol or character as x: Then, becaufe by the aforefaid propofition the ratio compounded of that which the focal diftance bears to the diftance of the radiant point (that is, in this fuppofition, of x to 20), and of the ratio which the diftance of the fame radiant point from the centre bears to the diftance between the centre and the focus (in this cafe, of 25 to $x-5$), is equal to the ratio which the fine of the angle of incidence bears to the fine of the angle of refraction (that is, of 17 to 11), we fhall have, in the inftance before us, the following proportion, viz.

$$\left.\begin{array}{l} x : 20 \\ 25 : x-5 \end{array}\right\} : : 17 : 11;$$

and compounding them into one, which is done by multiplying the two firft parts together, we have $25x : 20x-100 : : 17 : 11$, and multiplying the extreme terms and middle terms together $340x-1700=275x$, which equation after due reduction gives $x=\frac{1700}{65}$.

In fome cafes which might have been put, the quantity 65 would have been negative; and then the quotient arifing from 1700, divided by that, would have been fo too: that is, x the focal diftance would have been negative; in which cafe, the focus muft have been taken on the contrary fide of the furface to that on which it was fuppofed to fall in ftating the problem; that is, it muft have been taken on the fame fide with the radiant point; for in calling the diftance between the centre and the focus $x-5$, it was fuppofed the focus would fall on the fame fide with the centre, or on that which is oppofite to the radiant point; becaufe otherwife that diftance muft have been expreffed by $x+5$; as any one may fee by infpection of the 13th or 14th figure, in which the focus of diverging rays entering a convex furface, is fuppofed to fall on the fame fide with the radiant point.

In like manner as this problem was performed, a general theorem may be raifed to folve it in all cafes whatfoever, by ufing characters inftead of figures; as every one who is not unacquainted with algebraic operations very well knows.

See this done, and applied to the paffage of rays through the furface of lenfes, in the following fection.

A method of determining the point which a ray, entering a fpherical furface at any given diftance from the vortex of it, converges to, or diverges from, after refraction at the fame. *From the Appendix to Molineux's Dioptrics.*

" PROP. To find the focus of any parcel of rays diverging from, or converging to, a given point in the axis of a fpherical lens [furface], and inclined thereto under the fame angle; the ratio of the fines in refraction being known.

" Let GL (fig. 6.) be the lens, P any point in its furface, V the pole [vertex] thereof, C the centre of the fphere whereof it is a fegment, O the object or point in the axis to or from which the rays do proceed, OP a given ray; and let the ratio of refraction be as r to s; make CR to CO as s to r for the immerfion of a ray, or as r to s for the emerfion, (that is, as the fines of the angles in the medium which the ray

Of Refraction.

ray enters, to their correſponding ſines in the medium out of which it comes); and laying CR from C towards O, the point R ſhall be the ſame for all the rays of the point O. Then draw the radius PC (if need be) continued, and with the centre R and diſtance OP ſweep a touch of an arch, interſecting PC in Q; the line QR being drawn ſhall be parallel to the refracted ray, and PF being made parallel thereto ſhall interſect the axis in the point F; which is the focus ſought. Or make it as CQ : CP : : CR : CF, and CF ſhall be the diſtance of the focus from the centre of the ſphere.

"Dem. Let fall the perpendiculars PX on the axis, CY on the given ray, and CZ on the refracted ray. By the conſtruction QF and PR are parallel, whence the triangles QRC and PFC are ſimilar, and CR to QR, as CF to PF; that is, CR to OP, as CF to PF. Now CF : PF : : CZ : PX *ob ſimilia triang.*; whence CR : OP : : CZ : PX, and CR : CZ : : OP : PX. Again, CR is to CO as the ſines of refraction by conſtruction; that is, as s to r, or r to s; and as CR to CZ, ſo (CO=) $\frac{r}{s}$ or $\frac{s}{r}$CR to $\frac{r}{s}$ or $\frac{s}{r}$CZ; and ſo is PO to PX: But as PO to PX, ſo CO to CY. *Ergo*, CY= $\frac{r}{s}$ or $\frac{s}{r}$CZ; that is, CY to CZ is as the ſines of refraction; but CY is the ſine of the angle of incidence, and CZ of the refracted angle. *Ergo conſtat propoſitio.*——

"Hitherto we have conſidered only oblique rays; it now remains to add ſomething concerning rays parallel to the axis: in this caſe the point O muſt be conſidered as infinitely diſtant, and conſequently OP, OC, and CR are all infinite: and OP and OC are in this caſe to be accounted as always equal, (ſince they differ but by a part of the radius of the ſphere GPVL, which is no part of either of them): wherefore the ratio of CR to OP will be always the ſame, *viz.* as s to r for immerging rays, and as r to s for thoſe that emerge. And by this propoſition CF is to PF in the ſame ratio. It remains therefore to ſhew on the baſe CP how to find all the triangles CPF, wherein CF is to PF in the ratio given by the degree of refraction. This problem has been very fully conſidered by the celebrated Dr Wallis in his late treatiſe of Algebra, p. 258, to which we refer; but we ſhall here repeat the conſtruction thereof. (See fig. 7. 8.)

Plate CCIX.

"Let GPVL be a lens, VC or PC the radius of its ſphere, and let it be required to find all the points f, f, ſuch as Cf may be to Pf in the given ratio of s to r for immerging rays, or as r to s for the emerging. Divide CV in K, and continue CV to F, that CK may be to VK, and CF to VF, in the propoſed ratio. Then divide KF equally in the point a, and with that centre ſweep the circle FKF; this circle being drawn, gives readily all the foci of the parallel rays OP, OP. For having continued CP till it interſect the circle in F, PF ſhall be always equal to Vf, the diſtance of the focus of each reſpective parcel of rays OP from the vertex or pole of the lens.

"To demonſtrate this, draw the pricked line VF, and by what is delivered by Dr Wallis in the above-cited place, VF and CF will be always in the ſame propoſed ratio. Again, Vf being made equal to PF, CF and Cf will be likewiſe equal, as are CP, VC; and the angles PCf, VCF, being *ad verticem*, are alſo equal: Wherefore Pf will be equal to VF, and conſequently Cf to Pf in the ſame ratio as CF to VF; whence, and by what foregoes, the points f, f, are the ſeveral reſpective foci of the ſeveral parcels of rays OP, OP. *Q. E. D.*

Of Refraction.

§ 2. *Of Glaſſes.*

Glass may be ground into eight different ſhapes at leaſt, for optical purpoſes, *viz.*

1. A *plane-glaſs*, which is flat on both ſides, and of equal thickneſs in all its parts, as A. Fig. 9.
2. A *plano-convex*, which is flat on one ſide, and convex on the other, as B.
3. A *double-convex*, which is convex on both ſides, as C.
4. A *plano-concave*, which is flat on one ſide, and concave on the other, as D.
5. A *double concave*, which is concave on both ſides, as E.
6. A *meniſcus*, which is concave on one ſide, and convex on the other, as F.
7. A *flat plano-convex*, whoſe convex ſide is ground into ſeveral little flat ſurfaces, as G.
8. A *priſm*, which has three flat ſides, and when viewed endwiſe appears like an equilateral triangle, as H.

Glaſſes ground into any of the ſhapes B, C, D, E, F, are generally called *lenſes*.

A right line LIK, (fig. 9.) going perpendicularly through the middle of a lens, is called the *axis of the lens*.

A ray of light Gh, (fig. 10.) falling perpendicularly on a plane glaſs EF, will paſs thro' the glaſs in the ſame direction $h\,i$, and go out of it into the air in the ſame right courſe iH.

A ray of light AB, falling obliquely on a plane glaſs, will go out of the glaſs in the ſame direction, but not in the ſame right line: for in touching the glaſs, it will be refracted in the line BC; and in leaving the glaſs, it will be refracted in the line CD.

A ray of light CD, (fig. 11.) falling obliquely on the middle of a convex glaſs, it will go forward in the ſame direction DE, as if it had fallen with the ſame degree of obliquity on a plane glaſs; and will go out of the glaſs in the ſame direction with which it entered: for it will be equally refracted at the points D and E, as if it had paſſed through a plane ſurface. But the rays CG and CI will be ſo refracted, as to meet again at the point F. Therefore, all the rays which flow from the point C, ſo as to go through the glaſs, will meet again at F; and if they go farther onward, as to L, they croſs at F, and go forward on the oppoſite ſides of the middle ray CDEF, to what they were in approaching it in the directions HF and KF.

When parallel rays, as ABC, (fig. 12.) fall directly upon a plano-convex glaſs DE, and paſs through it, they will be ſo refracted, as to unite in a point f behind it: and this point is called the *principal focus*; the diſtance of which, from the middle of the glaſs, is called the *focal diſtance*, which is equal to twice the radius of the ſphere of the glaſs's convexity. And,

When parallel rays, as ABC, (fig. 13.) fall directly upon

Of Refraction.

Plate CCIX.

upon a glaſs DE, which is equally convex on both ſides, and paſs through it; they will be ſo refracted, as to meet in a point or principal focus f, whoſe diſtance is equal to the radius or ſemidiameter of the ſphere of the glaſs's convexity. But if a glaſs be more convex on one ſide than one the other, the rule for finding the focal diſtance is this: As the ſum of the ſemidiameters of both convexities is to the ſemidiameter of either, ſo is double the ſemidiameter of the other to the diſtance of the focus. Or divide the double product of the radii by their ſum, and the quotient will be the diſtance ſought.

Since all thoſe rays of the ſun which paſs through a convex glaſs are collected together in its focus, the force of all their heat is collected into that part; and is in proportion to the common heat of the ſun, as the area of the glaſs is to the area of the focus. Hence we ſee the reaſon why a convex glaſs cauſes the ſun's rays to burn after paſſing through it.

All theſe rays croſs the middle ray in the focus f, and then diverge from it, to the contrary ſides, in the ſame manner FfG, as they converged in the ſpace DfE in coming to it.

If another glaſs FG, of the ſame convexity as DE, be placed in the rays at the ſame diſtance from the focus, it will refract them ſo, as that, after going out of it, they will be all parallel, as *a b c;* and go on in the ſame manner as they came to the firſt glas DE, thro' the ſpace ABC; but on the contrary ſides of the middle ray Bfb: for the ray ADf will go on from f in the direction fGa, and the ray CEf in the direction fFc; and ſo of the reſt.

The rays diverge from any radiant point, as from a principal focus: Therefore if a candle be placed at f, in the focus of the convex glaſs FG, the diverging rays in the ſpace FfG will be ſo refracted by the glaſs, as that, after going out of it, they will become parallel, as ſhewn in the ſpace *c b a*.

If the candle be placed nearer the glaſs than its focal diſtance, the rays will diverge after paſſing thro' the glaſs more or leſs as the candle is more or leſs diſtant from the focus.

If the candle be placed farther from the glaſs than its focal diſtance, the rays will converge after paſſing thro' the glaſs, and meet in a point, which will be more or leſs diſtant from the glaſs as the candle is nearer to or farther from its focus: and where the rays meet, they will form an inverted image of the flame of the candle; which may be ſeen on a paper placed in the meeting of the rays.

Hence, if any object ABC (fig. 15.) be placed beyond the focus F of the convex glaſs *d e f*, ſome of the rays which flow from every point of the object, on the ſide next the glaſs, will fall upon it; and after paſſing through it, they will be converged into as many points on the oppoſite ſide of the glaſs, where the image of every point will be formed, and conſequently the image of the whole object, which will be inverted. Thus, the rays Ad, Ae, Af, flowing from the point A, will converge in the ſpace *d a f*, and by meeting at a, will there form the image of the point A. The rays Bb, Be, Bf, flowing from the point B, will be united at b by the refraction of the glaſs, and will there form the image of the point B. And the rays Cd, Ce, Cf, flowing from the point C, will be united at c, where they will form the image of the point C. And ſo of all the other intermediate points between A and C. The rays which flow from every particular point of the object, and are united again by the glaſs, are called *pencils of rays*.

Of Refraction.

If the object ABC be brought nearer to the glaſs, the picture *a b c* will be removed to a greater diſtance. For then more rays flowing from every ſingle point, will fall more diverging upon the glaſs; and therefore cannot be ſo ſoon collected into the correſponding points behind it. Conſequently, if the diſtance of the object ABC (fig. 16.) be equal to the diſtance eB of the focus of the glaſs, the rays of each pencil will be ſo refracted by paſſing through the glaſs, that they will go out of it parallel to each other; as dI, eH, fh, from the point C; dG, eK, fD, from the point B; and dK, eE, fL, from the point A: and therefore, there will be no picture formed behind the glaſs.

If the focal diſtance of the glaſs, and the diſtance of the object from the glaſs, be known, the diſtance of the picture from the glaſs may be found by this rule, viz. Multiply the diſtance of the focus by the diſtance of the object, and divide the product by their difference; the quotient will be the diſtance of the picture.

The picture will be as much bigger or leſs than the object, as its diſtance from the glaſs is greater or leſs than the diſtance of the object. For, as Be (fig. 15.) is to eB, ſo is AC to ca. So that if ABC be the object, *c b a* will be the picture; or if *c b a* be the object, ABC will be the picture. 114

How to find the focus of any lens.

For determining the progreſs of the rays after refraction by any lens, whatever be its form or matter, Mr Rowning gives the following method. "Suppoſe GH (fig. 14.) to be a given lens, and E a point in its axis from whence the diverging rays EL, &c. fall upon the lens, AL, the radius of the firſt convexity, and CK that of the ſecond; let LKf be the direction of the diverging ray EL after its refraction at the firſt ſurface, and KF its direction after refraction at both. Then will f be the focus of the rays after their firſt refraction, and F the point they will meet in after both. Let BD be the thickneſs of the lens, and let the proportion which the ſine of the angle of incidence bears to the ſine of the angle of refraction be expreſſed by the ratio of I to R. Call EB, d; BD, t; AB, r; CD, s; Bf, x; DF, y: Now, to find f their focus after refraction at L where they enter the firſt ſurface of the lens, comes under the third propoſition abovementioned: according to which the ratio compounded of x, the focal diſtance ſought, to d, the diſtance of the radiant point; and of $d+r$, the diſtance between the ſame point and the centre, to $x-r$, the diſtance between the centre and the focus, is as I to R; compounding theſe two ratios therefore (that is, multiplying them together) we have $dx+rx : dx-dr :: \mathrm{I} : \mathrm{R}$; which proportion being converted into an equation, and duly reduced, gives $x=\frac{\mathrm{I}dr}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r}$.

Thus having found the diſtance Bf, and conſequently the point f, to which the rays converge from L, we muſt proceed to find F, that to which they will converge after having paſſed through K, where they ſuffer a

a second refraction: this comes under the same proposition. But, if we would use the same letters as before, to express the proportion which the sine of the angle of incidence bears to that of the angle of refraction, they must be put one for the other; because, when rays pass out of a denser into a rarer medium, the sine of the angle of incidence bears the same proportion to the sine of the angle of refraction, that the sine of the angle of refraction does to the sine of the angle of incidence, when they pass out of a rarer into a denser. This being observed, by the aforesaid proposition, we shall have the ratio compounded of y, the focal distance, to $\frac{\mathrm{I}dr}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r}-t$, the imaginary focus in the incident rays, and of $\frac{\mathrm{I}dr}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r}-t+s$, the distance between the imaginary focus and the centre, to $y+s$, the distance between the centre and the focus, as R to I. Which equation, if we reduce the mixed quantities $\frac{\mathrm{I}dr}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r}-t$, and $\frac{\mathrm{I}dr}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r}-t+s$, into improper fractions, will stand thus:

$$\left.\begin{array}{c} y : \dfrac{\mathrm{I}dr-\mathrm{I}dt+\mathrm{R}dt+\mathrm{R}rt}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r} \\ \text{and} \\ \dfrac{\mathrm{I}dr-\mathrm{I}dt+\mathrm{R}dt+\mathrm{R}rt+\mathrm{I}ds-\mathrm{R}ds-\mathrm{R}rs}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r} : y+s \end{array}\right\} :: \mathrm{R} : \mathrm{I}.$$

And, compounding these ratios, we have

$$\frac{\mathrm{I}dry-\mathrm{I}dty+\mathrm{R}dty+\mathrm{R}rty+\mathrm{I}dsy+\mathrm{R}dsy-\mathrm{R}rsy}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r} : \frac{\mathrm{I}dry-\mathrm{I}dty+\mathrm{R}dty+\mathrm{R}rty+\mathrm{I}drs-\mathrm{I}dts-\mathrm{R}dts+\mathrm{R}rts}{-\mathrm{R}r} :: \mathrm{R} : \mathrm{I}.$$

And throwing out the two equal denominartors $\mathrm{I}d-\mathrm{R}d-\mathrm{R}r$, and $\mathrm{I}d-\mathrm{R}d-\mathrm{R}r$, and multiplying extremes together and means together, we have $\mathrm{II}dry-\mathrm{II}dty+\mathrm{IR}dty+\mathrm{IR}rty+\mathrm{II}dsy-\mathrm{IR}dsy-\mathrm{IR}rsy=\mathrm{IR}dry-\mathrm{IR}dty+\mathrm{RR}dty+\mathrm{RR}rty+\mathrm{IR}drs-\mathrm{IR}dts+\mathrm{RR}dts+\mathrm{RR}rts$; which equation being reduced, gives

$$y=\frac{\mathrm{IR}drs-\mathrm{IR}dts+\mathrm{RR}dts+\mathrm{RR}rts}{\mathrm{II}dr-\mathrm{II}dt+\mathrm{I}2\mathrm{R}dt+\mathrm{IR}rt+\mathrm{II}ds-\mathrm{IR}ds-\mathrm{IR}rs-\mathrm{IR}dr-\mathrm{RR}dt-\mathrm{RR}rt}.$$

This theorem may be applied to all cases whatever; even to plane surfaces *mutatis mutandis*, *v. g.* the radius of a concave surface being negative (as lying the contrary way) with respect to that of a convex, and the radius of a plain surface being an infinite line. If we would apply this theorem to a concave surface, we must change all the signs of those members wherein the symbol expressing the radius of that surface occurs; and if to a plane surface, all the members which involve the radius must be considered as infinite quantities: that is, all, except them, must be struck out of the equation as nothing. So, likewise, if we would have it extend to other rays besides diverging ones, the point where converging rays would meet, lying on the contrary side to that from whence the diverging ones were supposed to flow, its distance must be made negative; and the distance where parallel rays meet being infinite, it is only changing the signs of all those members in which d is found, if the rays are supposed converging; or making those members infinite, in case the rays are supposed parallel; which is done by striking out all the rest, as bearing no proportion to them.

§ 3. *Of Vision.*

Having described how the rays of light, flowing from objects, and passing through convex glasses, are collected into points, and form the images of the objects; it will be easy to understand how the rays are affected by passing through the humours of the eye, and are thereby collected into innumerable points on the bottom of the eye, and thereon form the images of the objects which they flow from. For, the different humours of the eye, and particularly the crystalline humour, are to be considered as a convex glass; and the rays in passing through them to be affected in the same manner as in passing through a convex glass. A description of the coats and humours, &c. has been given at large in anatomy: but for the reader's convenience in this place, we shall repeat in a few words as much of the description as will be sufficient for our present purpose.

The eye is nearly globular. It consists of three coats and three humours. The part DHHG of the outer coat, is called the *sclerotica;* the rest, DEFG, the *cornea*. Next within this coat is that called the *choroides*, which serves as it were for a lining to the other, and joins with the iris, *mn*, *mn*. The iris is composed of two sets of muscular fibres; the one of a circular form, which contracts the hole in the middle called the *pupil*, when the light would otherwise be too strong for the eye; and the other of radial fibres, tending every where from the circumference of the iris towards the middle of the pupil; which fibres, by their contraction, dilate and enlarge the pupil when the light is weak, in order to let in the more of its rays. The third coat is only a fine expansion of the optic nerve L, which spreads like net-work all over the inside of the choroides, and is therefore called the *retina;* upon which are painted (as it were) the images of all visible objects, by the rays of light which either flow or are reflected from them. Plate CCX. fig. 1. 115 Description of the eye.

Under the cornea is a fine transparent fluid like water, which is therefore called the *aqueous humour*. It gives a protuberant figure to the cornea, fills the two cavities *mm* and *nn*, which communicate by the pupil P; and has the same limpidity, specific gravity, and refractive power, as water. At the back of this lies the crystalline humour II, which is shaped like a double convex glass; and is a little more convex on the back than the fore part. It converges the rays, which pass through it from every visible object to its focus at the bottom of the eye. This humour is transparent like crystal, is much of the consistence of hard jelly, and exceeds the specific gravity of water in the proportion of 11 to 10. It is inclosed in a fine transparent membrane, from which proceed radial fibres *oo*, called the *ligamentum ciliare*, all around its edge; and join to the circumference of the iris.

At the back of the crystalline, lies the vitreous humour KK, which is transparent like glass, and is largest of all in quantity, filling the whole orb of the eye, and giving it a globular shape. It is much of a consistence with the white of an egg, and very little exceeds the specific gravity and refractive power of water.

As every point of an object ABC, (*ibid.*) sends out

Of Refraction.

out rays in all directions, some rays, from every point on the side next the eye, will fall upon the cornea between E and F; and by passing on thro' the humours and pupil of the eye, they will be converged to as many points on the retina or bottom of the eye, and will thereon form a distinct inverted picture *c b a* of the object. Thus, the pencil of rays *q r s* that flows from the point A of the object, will be converged to the point *a* on the retina; those from the point B will be converged to the point *b*; those from the point C will be converged to the point *c*; and so of all the intermediate points; by which means the whole image *a b c* is formed, and the object made visible: altho' it must be owned, that the method by which this sensation is carried from the eye by the optic nerve to the common sensory in the brain, and there discerned, is above the reach of our comprehension.

But that vision is effected in this manner, may be demonstrated experimentally. Take a bullock's eye whilst it is fresh; and having cut off the three coats from the back part, quite to the vitreous humour, put a piece of white paper over that part, and hold the eye towards any bright object, and you will see an inverted picture of the object upon the paper.

116 Why we see objects upright.

Since the image is inverted, many have wondered why the object appears upright. But we are to consider, 1. That inverted is only a relative term: and, 2. That there is a very great difference between the real object and the means or image by which we perceive it. When all the parts of a distant prospect are painted upon the retina, they are all right with respect to one another, as well as the parts of the prospect itself; and we can only judge of an object's being inverted, when it is turned reverse to its natural position with respect to other objects which we see and compare it with.—If we lay hold of an upright stick in the dark, we can tell which is the upper or lower part of it, by moving our hand downward or upward; and know very well that we cannot feel the upper end by moving our hand downward. Just so we find by experience, that upon directing our eyes towards a tall object, we cannot see its top by turning our eyes downward, nor its foot by turning our eyes upward; but must trace the object the same way by the eye to see it from head to foot, as we do by the hand to feel it; and as the judgment is informed by the motion of the hand in one case, so it is also by the motion of the eye in the other.

Plate CCX.

In fig. 2. is exhibited the manner of seeing the same object ABC, by both the eyes D and E at once.

117 Optic nerve insensible of light.

When any part of the image *cba* falls upon the optic nerve L, the corresponding part of the object becomes invisible. On which account, nature has wisely placed the optic nerve of each eye, not in the middle of the bottom of the eye, but towards the side next the nose; so that whatever part of the image falls upon the optic nerve of one eye, may not fall upon the optic nerve of the other. Thus the point *a* of the image *c b a* falls upon the optic nerve of the eye D, but not of the eye E; and the point *c* falls upon the optic nerve of the eye E, but not of the eye D: and therefore, to both eyes taken together, the whole object ABC is visible.

The nearer that any object is to the eye, the larger is the angle under which it is seen, and the magnitude under which it appears. Thus to the eye D, (fig. 3.) the object ABC is seen under the angle APC; and its image *c b a* is very large upon the retina: but to the eye E, at a double distance, the same object is seen under the angle A*p*C, which is equal only to half the angle APC, as is evident by the figure. The image *c b a* is likewise twice as large in the eye D, as the other image *c b a* is in the eye E. In both these representations, a part of the image falls on the optic nerve, and the object in the corresponding part is invisible.

As the sense of seeing is allowed to be occasioned by the impulse of the rays from the visible object upon the retina of the eye, and forming the image of the object thereon, and that the retina is only the expansion of the optic nerve all over the choroides; it should seem surprising, that the part of the image which falls on the optic nerve should render the like part of the object invisible; especially as that nerve is allowed to be the instrument by which the impulse and image are conveyed to the common-sensory in the brain.

118 Proved by experiment.

That the part of the image which falls upon the middle of the optic nerve is lost, and consequently the corresponding part of the object is rendered invisible, is plain by experiment. For if a person fixes three patches, A, B, C, (fig. 4.) upon a white wall, at the height of the eye, and the distance of about a foot from each other, and places himself before them, shutting the right eye, and directing the left towards the patch C, he will see the patches A and C, but the middle patch B will disappear. Or, if he shuts his left eye, and directs the right towards A, he will see both A and C, but B will disappear; and if he directs his eye towards B, he will see both B and A, but not C. For whatever patch is directly opposite to the optic nerve N, vanishes. This requires a little practice, after which he will find it easy to direct his eye so as to lose the sight of whichever patch he pleases.

119 Dispute concerning the seat of vision.

This experiment, first tried by M. Mariotte, occasioned a new hypothesis concerning the seat of vision, which he supposed not to be in the retina, but in the choroides. An improvement was afterwards made upon it by M. Picard, who contrived that an object should disappear when both the eyes were kept open. He fastened upon a wall a round white paper, an inch or two in diameter; and by the side of it he fixed two marks, one on the right hand, and the other on the left, each at about 2 feet distance from the paper, and somewhat higher. He then placed himself directly before the paper, at the distance of 9 or 10 feet, and putting the end of his finger over against both his eyes, so that the left-hand mark might be hid from the right eye, and the right-hand mark from the left eye. Remaining firm in this posture, and looking steadily, with both eyes, on the end of his finger, the paper which was not at all covered by it would totally disappear. This, he says, is the more surprising, because, without this particular encounter of the optic nerves, where no vision is made, the paper will appear double, as is the case when the finger is not rightly placed.

M. Marriotte observes, that this improvement on his

his experiment, by M. Picard, is ingenious, but difficult to execute, since the eyes must be considerably strained in looking at any object so near to them as four inches; and proposes another not less surprising, and more easy. Place, says he, on a dark ground, two round pieces of white paper, at the same height, and three feet from one another; then place yourself opposite to them, at the distance of 12 or 13 feet, and hold your thumb before your eyes, at the distance of about eight inches, so that it may conceal from the right eye the paper that is to the left hand, and from the left eye the paper to the right hand. Then, if you look at your thumb steadily with both eyes, you will lose sight of both the papers; the eyes being so disposed, that each of them receives the image of one of the papers upon the base of the optic nerve, while the other is intercepted by the thumb.

M. Le Cat pursued this curious experiment a little farther than M. Marriotte had done. In the place of the second paper, he fixed a large white board, and observed, that at a proper distance he lost sight of a circular space in the centre of it. He also observed the size of the paper which is thus concealed from the sight, corresponding to several distances, which enabled him to ascertain several circumstances relating to this part of the structure of the eye more exactly than had been done before.

The manner in which this curious experiment is now generally made, and which is both the easiest with respect to the eye, and the most indisputable with respect to the fact, is the following. Let three pieces of paper be fastened upon the side of a room, about two feet asunder; and let a person place himself opposite to the middle paper, and, beginning near to it, retire gradually backwards, all the while keeping one of his eyes shut, and the other turned obliquely towards that outside paper which is towards the covered eye, and he will find a situation (which is generally at about five times the distance at which the papers are placed from one another), where the middle paper will entirely disappear, while the two outermost continue plainly visible; because the rays which come from the middle paper will fall upon the retina where the optic nerve is inserted.

It will not surprise any person, even those who are the strongest advocates for the retina being the place at which the pencils of rays are terminated, and consequently the proper seat of vision, that M. Mariotte was led by this remarkable observation to suspect the contrary. He not only did so; but, in consequence of attentively considering the subject, a variety of other arguments in favour of the choroides occurred to him, particularly his observation, that the retina is transparent, as well as the crystalline, and other humours of the eye, which he thought could only enable it to transmit the rays farther; and he could not persuade himself that any substance could be considered as being the termination of the pencils, and the proper seat of vision, at which the rays are not stopped in their progress.

He was farther confirmed in his opinion of the small degree of sensibility in the retina, and of the greater sensibility of the choroides, by observing that the pupil dilates itself in the shade, and contracts itself in a great light; which involuntary motion, he thought, was a clear proof that the fibres of the iris are extremely sensible to the action of light; and this part of the eye is only a continuation of the choroides (A). He also thought that the dark colour of the choroides was intended to make it more susceptible of the impression of light.

M. Pecquet, in answer to M. Mariotte's observation concerning the transparency of the retina, says, that it is very imperfectly so, resembling only oiled paper, or the horn that is used for lanterns; and besides, that its whiteness demonstrates it to be sufficiently opaque for stopping the rays of light, as much as is necessary for the purpose of vision; whereas, if vision be performed by means of those rays which are transmitted through such a substance as the retina, it must be very indistinct.

As to the blackness of the choroides, which M. Marriotte thought to be necessary for the purpose of vision, M. Pecquet observes, that it is not the same in all eyes, and that there are very different shades of it among the individuals of mankind, as also among birds, and some other animals, whose choroides is generally black; and that in the eyes of lions, camels, bears oxen, stags, sheep, dogs, cats, and many other animals, that part of the choroides which is the most exposed to light, very often exhibits colours as vivid as those of mother of pearl, or of the iris. He admits that there is a defect of vision at the insertion of the optic nerve; but he thought that it was owing to the blood-vessels of the retina, the trunks of which are so large in that place as to obstruct all vision.

To M. Pecquet's objection, founded on the opacity of the retina, M. Marriotte observes, that there must be a great difference betwixt the state of that substance in living and dead subjects; and as a farther proof of the transparency of the retina, and the power of the choroides beyond it to reflect light, he says, that if a lighted candle be held near to a person's eyes, and a dog, at the distance of eight or ten steps, be made to look at him, he would see a bright light in the dog's eyes, which he thought to proceed from the reflection of the light of the candle from the choroides of the dog, since the same appearance cannot be produced in the eyes of men, or other animals, whose choroides is black.

To M. Pecquet's remark concerning the blood vessels of the retina, M. Marriotte observes, that they are not large enough to prevent vision in every part of the base of the nerve, since the diameter of each of the two vessels occupy no more than $\frac{1}{8}$ part of it. Besides, if this were the cause of this want of vision, it would vanish gradually, and the space to which it is confined would not be so exactly terminated as it appears to be.

We must add, that M. Pecquet also observed, that notwithstanding the insensibility of the retina at the insertion of the optic nerve when the light is only moderate; yet that luminous objects, such as a bright candle placed at the distance of four or five paces, do not

(A) M. Musschenbroeck says, that in many animals, as the lion, camel, bear, ox, stag, sheep, dog, cat, and many birds, the choroides is not black, but blue, green, yellow, or some other colour. *Introductio*, Vol. II. p. 748.

not abſolutely diſappear, in the ſame circumſtances in which a white paper would; for that this ſtrong light may be perceived though the picture fall on the baſe of the nerve. " I cannot help ſuſpecting, however, (ſays Dr Prieſtley), that M. Pecquet did not make this obſervation with ſufficient care. A large candle makes no impreſſion on that part of my eye, though it is by no means able to bear a ſtrong light."

The common opinion was alſo favoured by the anatomical deſcription of ſeveral animals by the members of the French academy, and particularly their account of the ſea-calf and porcupine; in both of which the optic nerve is inſerted in the very axis of the eye, exactly oppoſite to the pupil, which was thought to leave no room to doubt, but that in theſe animals the retina is perfectly ſenſible to the impreſſion of light at the inſertion of the nerve. But this obſervation may deſerve to be reconſidered.

M. De la Hire took part with M. Pecquet, arguing in favour of the retina from the analogy of the ſenſes, in all of which the nerves are the proper ſeat of ſenſation. This philoſopher, however, ſuppoſed that the choroides receives the impreſſions of images, in order to tranſmit them to the retina.

M. Perrault alſo took the part of M. Pecquet againſt M. Marriotte, and in M. Perrault's works we have ſeveral letters that paſſed between theſe two gentlemen upon this ſubject.

This diſpute about the immediate inſtrument of viſion was revived upon the occaſion of an odd experiment of M. Mery, recorded in the memoirs of the French academy for 1704. He plunged a cat in water, and expoſing her eye to the ſtrong light of the ſun, obſerved that the pupil was not at all contracted by it; from which he concluded, that the contraction of the iris is not produced by the action of the light, but by ſome other circumſtance. For he contended that the eye receives more light in this ſituation than in the open air. At the ſame time he thought he obſerved that the retina of the cat's eye was tranſparent, and that he could ſee the opaque choroides beyond it; from which he concludes, that the choroides is the ſubſtance intended to receive the rays of light, and to be the chief inſtrument of viſion. But M. De la Hire replies to this argument of M. Mery, in a memoir for the year 1709, p. 119; in which he endeavours to ſhew that fewer rays enter the eye under water, and that in thoſe circumſtances it is not ſo liable to be affected by them. Beſides, it is obvious to be remarked, that the cat muſt be in great terror in this ſituation; and being an animal that has a very great voluntary power over the muſcles of the iris, and being now extremely attentive to every thing about her, ſhe might keep her eye open notwithſtanding the action of the light upon it, and though it might be very painful to her. We are informed, that when a cat is placed in a window through which the ſun is ſhining, and conſequently her iris nearly cloſed, if ſhe hear a ruſtling, like that which is made by a mouſe, on the outſide of the window, ſhe will immediately open her eyes to their greateſt extent, without in the leaſt turning her face from the light.

M. Le Cat took part with M. Marriotte in this controverſy, it being peculiarly agreeable to this general hypotheſis, *viz.* that the pia mater, of which the choroides is a production, and not the nerves themſelves, is the proper inſtrument of ſenſation. He thought that the change which takes place in the eyes of old people (the choroides growing leſs black with age) favoured his hypotheſis, as they do not ſee with that diſtinctneſs with which young perſons do. M. Le Cat ſuppoſed that the retina anſwers a purpoſe ſimilar to that of the ſcarf-ſkin, covering the papillæ pyramidales, which are the immediate organ of feeling, or that of the porous membrane which covers the glandulous papillæ of the tongue. The retina, he ſays, receives the impreſſion of light, moderates it, and prepares it for its proper organ, but is not itſelf ſenſible of it.

It muſt be obſerved, that M. Le Cat had diſcovered that the pia mater, after cloſely embracing and conſtringing the optic nerve at its entrance into the eye, divides into two branches, one of which cloſely lines the cornea, and at length is loſt in it, while the ſecond branch makes what is called the *choroides*, or *uvea*. He alſo ſhewed that the ſclerotica is an expanſion of the dura mater; and he ſent diſſections of the eye to the royal academy of ſciences in 1739, to prove theſe aſſertions, and ſeveral others which he had advanced in his *Traité des Sens*, that were contrary to the opinions of the celebrated Winſlow.

To theſe arguments in favour of the choroides, alleged by thoſe gentlemen among whom the ſubject was firſt diſcuſſed, Dr Prieſtley in his hiſtory adds the following that had eſcaped their notice, but which were ſuggeſted to him by his friend Mr Michell.

In order that viſion be diſtinct, the pencils of rays which iſſue from the ſeveral points of any object, muſt be collected either accurately, or at leaſt very nearly, to correſponding points in the eye, which can only be done upon ſome uniform ſurface. But the retina being of a conſiderable thickneſs, and the whole of it being uniformly nervous, and at leaſt nearly, if not perfectly, tranſparent, preſents no particular ſurface; ſo that, in whatever part of it the pencils be ſuppoſed to have their foci, the rays belonging to them will be ſeparated from one another, either before or after they arrive there, and conſequently viſion would be confuſed.

If we ſuppoſe the ſeat of viſion to be at the nearer ſurface of the retina, and the images of objects be formed by direct rays, a conſiderable degree of confuſion could not but ariſe from the light reflected by the choroides, in thoſe animals in which it is white, or coloured. On the other hand, it would be impoſſible that viſion ſhould be performed at this place by light reflected from the choroides, becauſe in many animals it is perfectly black, and reflects no light at all; and yet ſuch animals ſee even more diſtinctly than others. And we cannot but ſuppoſe that, in whatever manner viſion is effected, it is the ſame in the eyes of all animals.

If the ſeat of viſion be at the farther ſurface of the retina, and it be performed by direct rays, a white choroides could be of no uſe; and if it were by reflected rays, a black one could not anſwer the purpoſe.

It is likewiſe an argument in favour of the choroides being the organ of viſion, that it is a ſubſtance which receives a more diſtinct impreſſion from the rays of light than any other membrane in any part of the animal ſyſtem, excepting (and perhaps not excepting) that white cuticle which lies under the ſcales of fiſhes; whereas

whereas the retina is a ſubſtance on which the light makes an exceedingly faint impreſſion, and perhaps no impreſſion at all; ſince light, in paſſing out of one tranſparent medium into another immediately contiguous to it, ſuffers no refraction or reflection, nor are any of the rays abſorbed, unleſs there is ſome difference in the refracting power of the two media, which probably is not the caſe between the retina and the vitreous humour, which is in contact with it. And wherever the light is not affected by the medium it falls upon, we can hardly ſuppoſe the medium to receive any impreſſion from the light, the action being probably always mutual and reciprocal.

Beſides, the retina is ſo ſituated, as to be expoſed to many rays beſides thoſe which terminate in it, and which, therefore, cannot be ſubſervient to viſion, if it be performed there. Now this is not the caſe with the choroides, which is in no ſhape tranſparent, and has no reflecting ſubſtance beyond it.

It is, moreover, peculiarly favourable to the hypotheſis of the ſeat of viſion being in the choroides, that we can then ſee a ſufficient reaſon for the diverſity of its colour in different animals, according as they are circumſtanced with reſpect to viſion. In all terreſtrial animals, which have occaſion to make uſe of their eyes by night, the choroides is either of a bright white, or of ſome very vivid colour, which reflects the light very ſtrongly. On this account viſion may be performed with leſs light, but it cannot be with great diſtinctneſs, the reflection of the rays doubling their effect; ſince it muſt extend over ſome ſpace, all reflection being made at a diſtance from the reflecting body. Beſides, the choroides in brutes is not in general perfectly white, but a little inclined to blue; and is therefore, probably, better adapted to ſee by the fainter coloured light, which chiefly prevails in the night; and, we would add, is on the ſame account more liable to be ſtrongly impreſſed by the colours to which they are chiefly expoſed.

On the other hand, the choroides of birds in general, eſpecially eagles, hawks, and other birds of prey, is black; by which means they are able to ſee with the greateſt diſtinctneſs, but only in bright day-light. The owl, however, ſeeking her food by night, has the choroides white, like that of a cat. Laſtly, in the eyes of man, which are adapted to various uſes, the choroides is neither ſo black as that of birds, nor ſo white as that of thoſe animals who make the greateſt uſe of their eyes in the night.

As to a third hypotheſis, which is in effect that of M. De la Hire, which makes both the retina and the choroides equally neceſſary to viſion, and ſuppoſe it be performed by the impreſſion of light on the choroides communicated to the retina; Mr Michell obſerves, that the perceptions can hardly be ſuppoſed to be ſo acute, when the nerves, which are the chief inſtruments of ſenſation, do not receive the impreſſions immediately, but only after they have been communicated to another ſubſtance. Beſides, it muſt be more natural to ſuppoſe, that, when the principal impreſſion is made upon the choroides, it is communicated to the brain by its own proper nerves, which are abundantly ſufficient for the purpoſe.

120 Dimenſions of the ſpot in the eye where there is no viſion.

The dimenſions and preciſe form of the ſpot in the eye in which there is no viſion, were more accurately calculated by Daniel Bernoulli, in the following manner. He placed a piece of money O, fig. 1, upon the floor; and then ſhutting one of his eyes, and making a pendulum to ſwing, ſo that the extremity of it might be nearly in the line AO, he obſerved at what place C it began to be inviſible, and where it again emerged into view at A. Raiſing the pendulum higher and lower, he found other points, as H, N, P, G, B, at which it began to be inviſible; and others, as M, L, E, A, at which it began to be viſible again; and drawing a curve through them, he found that it was elliptical; and, with reſpect to his own eye, the dimenſions of it were as follows, OC was 23, AC 10, BD 3, DH 13, and EG 14; ſo that the centre being at F, the greater axis was to the leſs as 8 to 7. Plate CCXI.

From theſe *data*, the plane on which the figure was drawn being obliquely ſituated with reſpect to the eye, he found, that the place in the eye that correſponded to it was a circle, the diameter of which was a ſeventh part of the diameter of the eye, the centre of it being 27 parts of the diameter from the point oppoſite to the pupil, a little above the middle. He concludes with obſerving, that, in order that this ſpace in which there is no viſion, may be as ſmall as poſſible, it was neceſſary that the nerve ſhould enter the eye perpendicularly, and that both this end, and alſo its entering the eye at a diſtance from its axis, are gained by the particular manner in which the two optic nerves unite and become ſeparate again, by croſſing one another.

In favour of one of the obſervations of Mr Michell, concerning the uſe of the choroides in viſion, Dr Prieſtley obſerves, that Aquapendente mentions the caſe of a perſon at Piſa, who could ſee very well in the night, but very little or none at all in the day-time. This is alſo ſaid to be the caſe with thoſe white people among the blacks of Africa, and the inhabitants of the iſthmus of America, who, from this circumſtance, are called *moon-eyed*. Our author thinks it probable that their choroides is not of a dark colour, as it is in others of the human ſpecies; but white, or light coloured, as in thoſe animals which have moſt occaſion for their eyes in the night.

The following conſiderations in favour of the retina being the proper ſeat of viſion are worthy of remark.

Dr Porterfield obſerves, that the reaſon why there is no viſion at the enterance of the optic nerve into the eye, may be, that it wants that ſoftneſs and delicacy, which it has when it is expanded upon the choroides; and that, in thoſe animals in which that nerve is inſerted in the axis of the eye, it is obſerved to be equally delicate, and therefore probably equally ſenſible, in that place as in any other part of the retina. In general, the nerves, when conſtringed by their coats, have but little ſenſibility, in compariſon of what they are endued with when they are diveſted of them, and unfolded in a ſoft and pulpy ſubſtance.

Haller obſerves, that the choroides cannot be the univerſal inſtrument of viſion, becauſe that ſometimes in men and birds, but eſpecially in fiſhes, it is covered internally with a black mucus, through which the rays cannot penetrate. This writer ſpeaks of a fibrous membrane in the retina diſtinct from its pulpy ſubſtance. On theſe fibres, he conjectures, that the images of objects are painted.

M. De la Hire's argument in favour of the retina, from

Of Refraction.

from the analogy of the senses, is much strengthened by considering that the retina is a large nervous apparatus, immediately exposed to the impression of light; whereas the choroides receives but a slender supply of nerves, in common with the sclerotica, the conjunctiva, and the eyelids, and that its nerves are much less exposed to the light than the naked fibres of the optic nerve. Indeed, from anatomical considerations, one might imagine that any other part of the body was as sensible of the impression of light, as the choroides.

That the optic nerve is of principal use in vision is farther probable from several phenomena attending some of the diseases in which the sight is affected. When an amaurosis has affected one eye only, the optic nerve of that eye has been found manifestly altered from its sound state. Dr Priestley was present when Mr Hey examined the brain of a young girl, who had been blind of one eye, and saw that the optic nerve belonging to it was considerably smaller than the other; and he informed him, that, upon cutting into it, he found it to be much harder, and cineritious. Morgagni, indeed, mentions two cases, in one of which he found the optic nerves smaller than usual, and of a cineritious colour, when, upon inquiry, he was informed that the person had not been blind, though there might have been some defect in the sight of one of the eyes. In the other case, only one of the optic nerves was affected in that manner, and the eye itself was in other respects very perfect. Here, also, he was expressly told that the person was not blind of that eye: but it appears that he himself had not been acquainted with the persons whom he dissected; and there have been many cases of persons being blind of one eye, without knowing it themselves, for a considerable time.

Moreover, as the optic nerve is solely spent in forming the retina, so no function of the eye, not immediately subservient to vision, is affected by an amaurosis. On the contrary, those nerves which go to the choroides are found to retain, in this disease, their natural influence. The iris will contract in a recent gutta serena of one eye, if the other remains sound, and is suddenly exposed to a strong light. The sclerotis, conjunctiva, and eyelids, which receive their nerves from the same branches as the choroides retain their sensibility in this disorder.

The manner in which persons recover from an amaurosis, favours the supposition of the seat of vision being in the retina; since those parts which are the most distant from the insertion of the nerve recover their sensibility the soonest, being, in those places, the most pulpy and softest; whereas there is no reason to think that there is any difference in this respect in the different parts of the choroides. Mr Hey has been repeatedly informed, by persons labouring under an imperfect amaurosis, or gutta serena, that they could not, when looking at any object with one eye, see it so distinctly when it was placed directly opposite to the pupil, as when it was situated somewhat obliquely. And those persons whom he had known to recover from a perfect amaurosis, first discovered the objects whose images fell upon that part of the retina which is at the greatest distance from the optic nerve.

We shall conclude these remarks with observing, that, if the retina be as transparent as it is generally represented to be, so that the termination of the pencils must necessarily be either upon the choroides, or some other opaque substance interposed between it and the retina, the action and reaction occasioned by the rays of light being at the common surface of this body and the retina, both these mediums (supposing them to be equally sensible to the impression of light) may be equally affected; but the retina, being naturally much more sensible to this kind of impression, may be the only instrument by which the sensation is conveyed to the brain, though the choroides, or the black substance with which it is sometimes lined, may also be absolutely necessary for the purpose of vision. Indeed, when the reflection of the light is made at the common boundary of any two mediums, it is with no propriety that this effect is ascribed to one of them rather than the other; and the strongest reflections are often made back into the densest mediums, when they have been contiguous to the rarest, or even to a vacuum. This is not far from the hypothesis of M. De la Hire, and will completely account for the entire defect of vision at the insertion of the optic narve.

121 Of bright and obscure vision.

Vision is distinguished into *bright* and *obscure*, *distinct* and *confused*.—It is said to be bright, when a sufficient number of rays enter the pupil at the same time; obscure, when too few. It is distinct when each pencil of rays is collected into a focus exactly upon the retina; *confused*, when they meet before they come at it, or when they would pass it before they meet; for, in either of these last cases, the rays flowing from different parts of the object, will fall upon the same part of the retina, which must necessarily render the image confused and indistinct.—Now, that objects may appear with a due brightness, whether more or fewer rays proceed from them, we have a power of contracting or dilating the pupil by means of the muscular fibres of the iris, in order to take in more or fewer rays as occasion requires. But this power has its limits. In some animals it is much greater than in others; particularly in such as are obliged to seek their food by night, as well as by day, as in cats, &c.

122 Of distinct vision at different distances.

That the rays may be collected into points exactly upon the retina, that is, that objects may appear distinct, whether they be nearer or farther off, *i. e.* whether the rays proceeding from them diverge more or less, we have a power of contracting or relaxing the ligamenta ciliaria, and thereby altering the form of the crystalline humour, and with it the focal distance of the rays. Thus, when the object we view is far off, and the rays fall upon the pupil with a very small degree of divergency, we contract the *ligamenta ciliaria*, which, being concave towards the vitreous humour, do thereby compress it more than otherwise they would do: by this means it is made to press harder upon the backside of the crystalline humour, which is thereby rendered flatter; and thus the rays proceed farther before they meet in a focus, than otherwise they would have done. Add to this, that we dilate the pupils of our eyes (unless in cases where the light is so strong that it offends the eye), and thereby admit rays into them that are more diverging than those which would otherwise enter. And, when the rays come from an object that is very near, and there-

fore diverge too much to be collected into their reſpective foci upon the retina; by relaxing the *ligamenta ciliaria*, we give the cryſtalline a more convex form, by which means the rays are made to ſuffer a proportionably greater degree of refraction in paſſing through it. Some philoſophers are of opinion that we do this by a power of altering the form of the eye; and others, by removing the cryſtalline forwards or backwards as occaſion requires: but neither of theſe opinions is probable; for the coats of the eye are too hard, in ſome animals, for the firſt; and, as to moving the cryſtalline out of its place, the cavities of the eye ſeem to be too well filled with the other humours to admit of ſuch removal.

Beſides this, in the caſe above-mentioned, by contracting the pupils of our eyes, we exclude the more diverging rays, and admit only ſuch as are more eaſily refracted into their reſpective foci (A). But viſion is not diſtinct at all diſtances, for our power of contracting and relaxing the ligamenta ciliaria is alſo circumſcribed within certain limits.

123 Of ſhort-ſighted and long-ſighted people.

In thoſe eyes where the tunica cornea is very protuberant and convex, the rays of light ſuffer a very conſiderable refraction at their entrance into the aqueous humour, and are therefore collected into a focus before they fall upon the retina, unleſs the object be placed very near, ſo that the rays which enter the eye may have a conſiderable degree of divergency. People that have ſuch eyes are ſaid to be *purblind*. Now, the nearer an object is to the eye, the greater is the image of it therein, as explained above: theſe people therefore can ſee much ſmaller objects than others, as ſeeing much nearer ones with the ſame diſtinctneſs; and their ſight continues good longer than that of other people, becauſe the tunica cornea of their eyes, as they grow old, becomes plainer, for want of that redundancy of humours with which they were filled before. On the contrary, old men, having the cornea of their eyes too flat for want of a ſufficient quantity of the aqueous humour to fill them out, if the rays diverge too much before they enter the eye, they cannot be brought to a focus before they reach the retina; on which account thoſe people cannot ſee diſtinctly, unleſs the object be ſituated at a greater diſtance from the eye, than is required for thoſe whoſe eyes are of a due form. The latter require the aſſiſtance of convex glaſſes, to make them ſee objects diſtinctly; the former of concave ones. For if either the cornea *abc* (fig. 5.), or cryſtalline humour *e*, or both of them, be too flat, as in the eye A, their focus will not be on the retina as at A, where it ought to be, in order to render viſion diſtinct; but beyond the eye, as at *f*. This is remedied by placing a convex glaſs *gh* before the eye, which makes the rays converge ſooner, and imprints the image duely on the retina at *d*. Again, if either the cornea, or cryſtalline humour, or both of them, be too convex, as in the eye B, the rays that enter it from the object C will be converged to a focus in the vitreous humour, as at *f*; and by diverging from thence to the retina, will form a very confuſed image thereon; and ſo, of courſe, the obſerver will have as confuſed a view of the object as if his eye had been too flat. This inconvenience is remedied by placing a concave glaſs *gh* before the eye; which glaſs, by cauſing the rays to diverge between it and the eye, lengthens the focal diſtance ſo, that if the glaſs be properly choſen, the rays will unite at the retina, and form a diſtinct image of the object upon it.

Plate CCX.

124 Of the leaſt angle of viſion.

Such eyes as are of a due convexity, cannot ſee any object diſtinctly at leſs diſtance than ſix inches; and there are numberleſs objects too ſmall to be ſeen at that diſtance, becauſe they cannot appear under any ſenſible angle.—Concerning the leaſt angle under which any object is viſible, there was a debate between Dr Hooke and Hevelius. The former aſſerted, that no object could well be ſeen if it ſubtended an angle leſs than one minute; and, if the object be round, as a black circular ſpot upon a white ground, or a white circle upon a black ground, it follows, from an experiment made by Dr Smith, that this is near the truth; and from thence he calculates, that the diameter of the picture of ſuch leaſt viſible point upon the retina is the 8000th part of an inch; which he therefore calls a *ſenſible point of the retina*. On the other hand, Mr Courtivron concluded from his experiments, that the ſmalleſt angle of viſion was 40 ſeconds. According to Dr Jurin, there are caſes in which a much ſmaller angle than one minute can be diſcerned by the eye; and in order to throw light upon the ſubject, he obſerves, that, in order to our perceiving the impreſſion made by any object upon our ſenſes, it muſt either be of a certain degree of force, or of a certain degree of magnitude. For this reaſon a ſtar, which appears only as a lucid point through a teleſcope, ſubtending not ſo much as an angle of one ſecond, is viſible to the eye; though a white or black ſpot, of 25 or 30 ſeconds, is not to be perceived. Alſo a line of the ſame breadth with the circular ſpot will be viſible, at ſuch a diſtance as the ſpot is not to be perceived at; becauſe the quantity of impreſſion from the line is much greater than from the ſpot; and a longer line is viſible at a greater diſtance than a ſhorter one of the ſame breadth. He found by experience, that a ſilver wire could be ſeen when it ſubtended an angle of three ſeconds and an half; and that a ſilk thread could be ſeen when it ſubtended an angle of two ſeconds and a half.

125 Lines can be ſeen under ſmaller angles than ſpots, and why.

This greater viſibility of a line than of a ſpot, ſeems to ariſe only from the greater quantity of the impreſſion; but without the limits of perfect viſion, our author obſerves, that another cauſe concurs, whereby the difference of viſibility between the ſpot and the line is rendered much more conſiderable. For the impreſſion upon the retina made by the line is then not only much greater, but alſo much ſtronger than that of the ſpot; becauſe the faint image, or penumbra, of any one point of the line, when the whole is placed beyond the limits of diſtinct viſion, will fall within the faint image of the next point, and thereby much increaſe the light that comes from it.

In ſome caſes our author found the cauſe of indiſtinct viſion to be the unſteadineſs of the eye; as our being able to ſee a ſingle black line upon a white ground, or a ſingle white line upon a black ground, and

(A) Accordingly it is obſerved, that if we make a ſmall hole with the point of a needle through a piece of paper, and apply that hole cloſe to the eye, making uſe of it, as it were, inſtead of a pupil, we ſhall be able to ſee an object diſtinctly through it, though the object be placed within half an inch of the eye.

Of Refraction.

and not a white line between two black ones on a white ground. In viewing either of the former objects, if the eye be imperceptibly moved, all the effect will be, that the object will be painted upon a different part of the retina; but, wherever it is painted, there will be but one picture, single and uncompounded with any other. But in viewing the other, if the eye fluctuate ever so little, the image of one or other of the black lines will be shifted to that part of the retina which was before possessed by the white line; and this must occasion such a dazzle in the eye, that the white line cannot be distinctly perceived, and distinguished from the black lines; which, by a continual fluctuation, will alternately occupy the space of the white line, whence must arise an appearance of one broad dark line, without any manifest separation.

By trying this experiment with two pins of known diameters, set in a window against the sky light, with a space between them equal in breadth to one of the pins, he found that the distance between the pins could hardly be distinguished when it subtended an angle of less than 40 seconds, though one of the pins alone could be distinguished when it subtended a much less angle. But though a space between two pins cannot be distinguished by the eye when it subtends an angle less than 40 seconds, it would be a mistake to think that the eye must necessarily commit an error of 40 seconds in estimating the distance between two pins when they are much farther from one another. For if the space between them subtend an angle of one minute, and each of the pins subtend an angle of four seconds, which is greater than the least angle the eye can distinguish, it is manifest that the eye may judge of the place of each pin within two seconds at the most; and consequently the error committed in taking the angle between them cannot at the most exceed four seconds, provided the instrument be sufficiently exact. And yet, says he, upon the like mistake was founded the principal objection of Dr Hooke against the accuracy of the celestial observations of Hevelius.

A black spot upon a white ground, or a white spot upon a black ground, he says, can hardly be perceived by the generality of eyes when it subtends a less angle than one minute. And if two black spots be made upon white paper, with a space between them equal in breadth to one of their diameters, that space is not to be distinguished, even within the limits of perfect vision, under so small an angle as a single spot of the same size can be distinguished. To see the two spots distinctly, therefore, the breadth of the space between them must subtend an angle of more than a minute. It would be very difficult, he says, to make this experiment accurately, within the limits of perfect vision; because the objects must be extremely small: but by a rude trial, made with square bits of white paper, placed upon a black ground, he judged, that the least angle under which the interval of two objects could be perceived, was at least a fourth part greater than the least angle under which a single object can be perceived. So that an eye which cannot perceive a single object under a smaller angle than one minute, will not perceive the interval between two such objects under a less angle than 75 seconds.

Without the limits of perfect vision, the distance at which a single object ceases to be perceivable will be much greater in proportion than the distance at which a space of equal breadth between two such objects ceases to be perceivable. For, without these limits, the image of each of the objects will be attended with a penumbra, and the penumbra of the two near objects will take up part of the space between them, and thereby render it less perceivable; but the penumbra will add to the breadth of the single object, and will thereby make it more perceivable, unless its image be very faint. Upon the same principles he likewise accounts for the radiation of the stars, whereby the light seems to project from them different ways at the same time.

Mr Mayer made many experiments in order to ascertain the smallest angle of vision in a variety of respects. He began with observing at what distance a black spot was visible on white paper; and found, that when it could barely be distinguished, it subtended an angle of about 34 seconds. When black lines were disposed with intervals broader than themselves, they were distinguished at a greater distance than they could be when the objects and the intervals were of an equal breadth. In all these cases it made no difference whether the objects were placed in the shade, or in the strong light of the sun; but when the degrees of light were small, their differences had a considerable effect, though by no means in proportion to the differences of the light. For if an object was illuminated to such a degree as to be just visible at the distance of nine feet, it would be visible at the distance of four feet, tho' the light was diminished above 160 times. It appeared in the course of these experiments, that common day-light is, at a medium, equal to that of 25 candles placed at the distance of one foot from the object.

126 Of single vision with two eyes.

As an image of every visible object is painted on the retina of each of our eyes, it thence becomes a natural question, Why we do not see every thing double? It was the opinion of Sir Isaac Newton and others, that objects appear single because the two optic nerves unite before they reach the brain. But Dr Porterfield shews, from the observation of several anatomists, that the optic nerves do not mix, or confound their substance, being only united by a close cohesion; and objects have appeared single where the optic nerves were found to be disjoined.

Dr Briggs supposed that single vision was owing to the equal tension of the corresponding parts of the optic nerves, whereby they vibrated, in a synchronous manner. But, besides several improbable circumstances in this account, Dr Porterfield shews that facts do by no means favour it.

To account for this phenomenon, this ingenious writer supposes, that by an original law in our natures, we imagine objects to be situated somewhere in a right line drawn from the picture of it upon the retina, through the centre of the pupil. Consequently, the same object appearing to both eyes to be in the same place, the mind cannot distinguish it into two. In answer to an objection to this hypothesis, from objects appearing double when one eye is distorted, he says the mind mistakes the position of the eye, imagining that it had moved in a manner corresponding to the other, in which case the conclusion would have

have been just. In this he seems to have recourse to the power of habit, tho' in words he disclaims that hypothesis.

This principle, however, has generally been thought to be sufficient to account for this appearance. Originally, every object making two pictures, one in each eye, is imagined to be double; but, by degrees, we find, that when two corresponding parts of the retina are impressed, the object is but one; but if those corresponding parts be changed, by the distortion of one of the eyes, the object must again appear double as at the first. This seems to be verified by Mr Cheselden; who informs us, that a gentleman, who from a blow on his head had one eye distorted, found every object to appear double; but by degrees the most familiar ones came to appear single again, and in time all objects did so, without any amendment of the distortion. A case similar to this is mentioned by Dr Smith.

On the other hand, Dr Reid is of opinion, that the correspondence of the centres of the two eyes, on which single vision depends, does not arise from custom, but from some natural constitution of the eye and of the mind. He makes several just objections to the case of Mr Foster, recited by Dr Smith and others; and thinks that the case of the young man couched by Cheselden, who saw singly with both eyes immediately upon receiving his sight, is nearly decisive in proof of his supposition. He also found that three young gentlemen, whom he endeavoured to cure of squinting, saw objects singly, as soon as ever they were brought to direct the centres of both their eyes to the same object, though they had never been used to do so from their infancy; and he observes, that there are cases, in which, notwithstanding the fullest conviction of an object being single, no practice of looking at it will ever make it appear so, as when it is seen thro' a multiplying glass.

We are indebted to Dr Jurin for the following curious experiments to determine whether an object seen by both eyes appears brighter than when seen with one only.

He laid a slip of clean white paper directly before him on a table, and applying the side of a book close to his right temple, so as that the book was advanced considerably more forward than his face, he held it in such a manner, as to hide from his right eye that half of the paper which lay to his left hand, while the left half of the paper was seen by both eyes, without any impediment.

Then looking at the paper with both eyes, he observed it to be divided, from the top to the bottom, by a dark line, and the part which was seen with one eye only was manifestly darker than that which was seen with both eyes; and, applying the book to his left temple, he found, by the result of the experiment, that both his eyes were of equal goodness.

He then endeavoured to find to what degree this excess of brightness amounted; and comparing it with the appearance of an object illuminated partly by one candle and parly by two, he was surprised to find that an object seen with two eyes is by no means twice as luminous as when it is seen with one only; and after a number of trials, by which he made the proportion less and less continually, he found, that when one paper was illuminated by a candle placed at the distance of three feet, and another paper by the same candle at the same distance, and by another candle at the distance of 11 feet, the former seen by both eyes, and the latter with one eye only, appeared to be of equal whiteness; so that an object seen with both eyes appears brighter than when it is seen with one only by about a 13th part. But he acknowledges, that is difficult to make this experiment exactly.

He then proceeded to inquire, whether an object seen with both eyes appears any thing larger than when seen with one only; but he concluded that it did not, except on account of some particular circumstances, as in the case of the binocular telescope, and the concave speculum.

M. Du Tour maintains, that the mind attends to no more than the image made in one eye at a time; and produces several curious experiments in favour of this hypothesis, which had also been maintained by Kepler and almost all the first opticians. But, as M. Buffon observes, it is a sufficient answer to this hypothesis, how ingeniously soever it may be supported, that we see more distinctly with two eyes than one; and that when a round object is near us we plainly see more of the surface in one case than in the other. There are, also, other facts, which clearly prove the contrary of what is maintained by M. Du Tour.

With respect to single vision with two eyes, Dr Hartley observes, that it deserves particular attention, that the optic nerves of men, and such other animals as look the same way with both eyes, unite in the *sella turcica* in a ganglion, or little brain, as one may call it, peculiar to themselves; and that the associations between synchronous impressions on the two retinas must be made sooner and cemented stronger on this account; also that they ought to have a much greater power over one another's images, than in any other part of the body. And thus an impression made on the right eye alone, by a single object, may propagate itself into the left, and there raise up an image almost equal in vividness to itself; and consequently when we see with one eye only, we may, however, have pictures in both eyes.

A curious deception in vision, arising from the use of both eyes, was observed and accounted for by Dr Smith. It is a common observation, he says, that objects seen with both eyes appear more vivid and stronger than they do to a single eye; especially when both of them are equally good. A person not short-sighted may soon be convinced of this fact, by looking attentively at objects that are pretty remote, first with one eye, and then with both. This observation gave occasion to the construction of the binocular telescope, in the use of which the phenomenon is still more striking.

Besides this, our author observes, that there is another phenomenon observable with this instrument, which is very remarkable. In the foci of the two telescopes there are two equal rings, as usual, which terminate the pictures of the objects there formed, and consequently the visible area of the objects themselves. These equal rings, by reason of the equal eye-glasses, appear equal, and equally distant when seen separately by each eye; but when they are seen with both eyes, they appear much larger, and more distant also; and the

Of Refraction.

the objects seen through them do also appear much larger, though circumscribed by their united rings, in the same places as when they were seen separately.

He observes, that the phenomenon of the enlarged circle of the visible area in the binocular telescope, may be seen very plainly in looking at distant objects through a pair of spectacles, removed from the eyes about four or five inches, and held steady at that distance. The two innermost of the four apparent rings, which hold the glasses, will then appear united in one larger and more distant ring than the two outermost, which will hardly be visible unless the spectacles be farther removed.

A curious circumstance relating to the effect of one eye upon the other, was noticed by M. Æpinus, who observed, that, when he was looking through a hole made in a plate of metal, about the 10th part of a line in diameter, with his left eye, both the hole itself appeared larger, and also the field of view seen thro' it was more extended, whenever he shut his right eye; and both these effects were more remarkable when that eye was covered with his hand. He found considerable difficulty in measuring this augmentation of the apparent diameter of the hole, and of the field of view; but at length he found, that, when the hole was half an inch, and the tablet which he viewed through it was three feet from his eye, if the diameter of the field when both his eyes were open was 1, it became $1\frac{1}{2}$ when the other eye was shut, and nearly 2 when his hand was laid upon it.

Upon examining this phenomenon, it presently appeared to depend upon the enlargement of the pupil of one eye when the other is closed, the physical or anatomical cause of which he did not pretend to assign; but he observes, that it is wisely appointed by divine Providence, in order that when one eye fails, the field of view in the other may be extended. That this effect should be more sensible when the eye is covered with the hand, is owing, he observes, to the eye-lids not being impervious to the light. But the enlargement of the pupil does not enlarge the field of view, except in looking through a hole, as in this particular case; and therefore persons who are blind of one eye can derive no advantage from this circumstance. Before we applaud the wisdom of Providence in any part of the constitution of nature, we should be very sure that we do not mistake concerning the effects of that constitution.

A great deal has been written by Gassendi, Le Clerc, Muschenbroek, and Du Tour, concerning the place to which we refer an object viewed by one or both eyes. But the subject is not of much consequence. Any person may presently satisfy himself with respect to every thing belonging to this circumstance, either by experiment, holding his finger before his eyes, and looking at it and an object beyond it; or by figures, in which lines representing the optic axes may be made to cross one another at different distances from the eye.

§ 4. *Of the Appearance of Objects seen through Media of different Forms.*

For the more easy apprehension of what relates to this subject, we shall premise the five following particulars, which either have been already mentioned, or follow from what has been before laid down.

Of Refraction.

1. That as each point of an object, when viewed by the naked eye, appears in its proper place; and as that place is always to be found in the line in which the axis of a pencil of rays flowing from it enters the eye; we from hence acquire an habit of judging the point to be situated in that line: and, because the mind is unacquainted with what refractions the rays suffer before they enter the eye, therefore, in cases where they are diverted from their natural course, by passing through any medium, it judges the point to be in that line produced back in which the axis of a pencil of rays flowing from it is situated the instant they enter the eye, and not in that it was in before refraction. We shall therefore, in what follows, suppose the apparent place of an object, when seen thro' a refracting medium, to be somewhere in that line produced back in which the axis of a pencil of rays flowing from it proceeds after they have passed through the medium.

2. That we are able to judge, though imperfectly, of the distance of an object by the degree of divergency, wherein the rays flowing from the same point of the object enter the pupil of the eye, in cases where that divergency is considerable; but because in what follows it will be necessary to suppose an object, when seen through a medium whereby its apparent distance is altered, to appear in some determinate situation, in those cases where the divergency of the rays at their entrance into the eye is considerable, we will suppose the object to appear where those lines which they describe in entering, if produced back, would cross each other: though it must not be asserted, that this is the precise distance; because the brightness, distinctness, and apparent magnitude of the object, on which its apparent distance in some measure depends, will also suffer an alteration by the refraction of the rays in passing through that medium.

3. That we estimate the magnitude of an object by that of the optic angle.

4. That vision is the brighter, the greater the number of rays is which enter the pupil. And,

5. That, in some cases, the apparent brightness, distinctness, and magnitude of an object, are the only means whereby our judgment is determined in estimating the distance of it.

Prop. I. An object placed within a medium terminated by a plane surface on that side which is next the eye, if the medium be denser than that in which the eye is (as we shall always suppose it to be, unless where the contrary is expressed), appears nearer to the surface of the medium than it is.

Thus, if A be a point of an object placed within the medium BDCE (fig. 2.), and A b A c be two rays proceeding from thence, these rays passing out of a denser into a rarer medium, will be refracted from their respective perpendiculars $b\,d$, $c\,e$, and will enter the eye at H, suppose in the directions bf, cg, let then these lines be produced back till they meet in F; this will be the apparent place of the point A: and because the refracted rays bf, cg will diverge more than the incident ones A b, A c, it will be nearer to the points b and c, than the point A; and as the same is true of each point in the object, the whole

Plate CCXI.

whole will appear to an eye at H, nearer to the surface BC than it is.

From hence it is, that when one end of a straight stick is put under water, and the stick is held in an oblique position, it appears bent at the surface of the water; viz. because each point that is under water appears nearer the surface, and consequently higher than it is.

From hence likewise it is, that an object at the bottom of a vessel may be seen when the vessel is filled with water, though it be so placed with respect to the eye, that it cannot be seen when the vessel is empty. To explain this, let ABCD (fig. 3.) represent a vessel, and let E be an object lying at the bottom of it. This object, when the vessel is empty, will not be seen by an eye at F, because HB, the upper part of the vessel, will obstruct the ray EH; but when it is filled with water to the height GH, the ray EK being refracted at the surface of the water into the line KF, the eye at F shall see the object by means of that.

Plate CCXI.

In like manner, an object situated in the horizon appears above its true place, upon account of the refraction of the rays which proceed from it in their passage through the atmosphere of the earth. For, first, if the object be situated beyond the limits of the atmosphere, its rays in entering it will be refracted towards the perpendicular; that is, towards a line drawn from the point where they enter, to the centre of the earth, which is the centre of the atmosphere: and as they pass on, they will be continually refracted the same way, because they are all along entering a denser part, the centre of whose convexity is still the same point; upon which account the line they describe will be a curve bending downwards: and therefore none of the rays that come from that object can enter an eye upon the surface of the earth, except what enter the atmosphere higher than they need to do if they could come in a right line from the object: consequently the object must appear above its proper place. Secondly, if the object be placed within the atmosphere, the case is still the same; for the rays which flow from it must continually enter a denser medium whose centre is below the eye; and therefore being refracted towards the centre, that is, downwards as before, those which enter the eye must necessarily proceed as from some point above the object; wherefore the object will appear above its proper place.

From hence it is, that the sun, moon, and stars, appear above the horizon, when they are just below it; and higher than they ought to do, when they are above it: Likewise distant hills, trees, &c. seem to be higher than they are.

Further, the lower these objects are in the horizon, the greater is the obliquity with which the rays which flow from them enter the atmosphere, or pass from the rarer into the denser parts of it; and therefore they appear to be the more elevated by refraction: upon which account the lower parts of them are apparently more elevated than the other. This makes their upper and under parts seem nearer than they are; as is evident from the sun and moon, which appear of an oval form when they are in the horizon, their horizontal diameters appearing of the same length they would do if the rays suffered no refraction, while their vertical ones are shortened thereby.

Prop. II. An object seen through a medium terminated by plane and parallel surfaces, appears nearer, brighter, and larger, than with the naked eye.

For instance, let AB (fig. 4.) be the object, CDEF the medium, and GH the pupil of an eye, which is here drawn large to prevent confusion in the figure. And, 1st, let RK, RL, be two rays proceeding from the point R, and entering the denser medium at K and L; these rays will here by refraction be made to diverge less, and to proceed afterwards, suppose in the lines K*a*, L*b*; at *a* and *b*, where they pass out of the denser medium, they will be as much refracted the contrary way, proceeding in the lines *ac*, *bd*, parallel to their first directions. Produce these lines back till they meet in *e*: this will be the apparent place of the point R; and it is evident from the figure, that it must be nearer the eye than that point; and because the same is true of all other pencils flowing from the object AB, the whole will be seen in the situation *fg*, nearer to the eye than the line AB. 2d, As the rays RK, RL, would not have entered the eye, but have passed by it in the directions K*r*, L*t*, had they not been refracted in passing through the medium, the object appears brighter. 3d, The rays A*h*, B*i*, will be refracted at *h* and *i* into the less converging lines *hk*, *il*, and at the other surface into *k*M, *l*M, parallel to A*h* and B*i* produced; so that the extremities of the object will appear in the lines M*k*, M*l* produced, viz. in *f* and *g*, and under as large an angle *f*M*g*, as the angle A*q*B under which an eye at *q* would have seen it had there been no medium interposed to refract the rays; and therefore it appears larger to the eye at GH, being seen through the interposed medium, than otherwise it would have done. But it is here to be observed, that the nearer the point *e* appears to the eye on account of the refraction of the rays RK, RL, the shorter is the image *fg*, because it is terminated by the lines M*f* and M*g*, upon which account the object is made to appear less; and therefore the apparent magnitude of an object is not much augmented by being seen through a medium of this form.

Farther, it is apparent from the figure, that the effect of a medium of this form depends wholly upon its thickness; for the distance between the lines R*r* and *ec*, and consequently the distance between the points *e* and R, depends upon the length of the line K*a*: Again, the distance between the lines AM and *f*M, depends on the length of the line *hk*; but both K*a* and *kh* depend on the distance between the surfaces CE and DF, and therefore the effect of this medium depends upon its thickness.

Prop. III. An object seen through a convex lens, appears larger, brighter, and more distant, than with the naked eye.

To illustrate this, let AB (fig. 5.) be the object, CD the lens, and EF the eye. 1. From A and B, the extremities of the object, draw the lines AY*r*, BX*r*, crossing each other in the pupil of the eye; the angle A*r*B comprehended between these lines, is the angle under which the object would be seen with the naked eye. But by the interposition of a lens of this form, whose property it is to render converging rays more so, the

Of Refraction.

Plate CCXI. fig. 5.

the rays AY and BX will be made to crofs each other before they reach the pupil. There the eye at E will not perceive the extremities of the object by means of thefe rays (for they will pafs it without entering), but by fome others which muft fall without the points Y and X, or between them; but if they fall between them, they will be made to concur fooner than they themfelves would have done; and therefore, if the extremities of the object could not be feen by them, it will much lefs be feen by thefe. It remains therefore, that the rays which will enter the eye from the points A and B after refraction, muft fall upon the lens without the points Y and X; let then the rays AO and BP be fuch. Thefe after refraction entering the eye at r, the extremities of the object will be feen in the lines rQ, rT, produced, and under the optic angle QrT, which is larger than ArB, and therefore the apparent magnitude of the object will be increafed. 3. Let GHI be a pencil of rays flowing from the point G; as it is the property of this lens to render diverging rays lefs diverging, parallel, or converging, it is evident, that fome of thofe rays, which would proceed on to M and N, and mifs the eye, were they to fuffer no refraction in paffing through the lens, will now enter it; by which means the object will appear brighter. 3. As to the apparent diftance of the object, that will vary according to the fituation of it with refpect to the focus of parallel rays of the lens. 1. Then, let us fuppofe the object placed fo much nearer the lens than its focus of parallel rays, that the refracted rays KE and LF, though rendered lefs diverging by paffing through it, may yet have a confiderable degree of divergency, fo that we may be able to form a judgment of the diftance of the object thereby. In this cafe, the object ought to appear where EK, FL, produced back concur; which, becaufe they diverge lefs than the rays GH, GI, will be beyond G, that is, at a greater diftance from the lens than the object is. But becaufe both the brightnefs and magnitude of the object will at the fame time be augmented, prejudice will not permit us to judge it quite fo far off as the point where thofe lines meet, but fomewhere between that point and its proper place. 2. Let the object be placed in the focus of parallel rays, then will the rays KE and LF become parallel; and though in this cafe the object would appear at an immenfe diftance, if that diftance were to be judged of by the direction of the rays KE and LF, yet upon account of the brightnefs and magnitude of it, we fhall not think it much farther from us than if it were feen by the naked eye. 3. If the object be fituated beyond the focus of parallel rays, as in BA (fig. 6.) the rays flowing from thence and falling upon the lens CD, will be collected into their refpective foci at a and b, and the intermediate points m, n, &c. and will there form an image of the object AB; and after croffing each other in the feveral points of it, as expreffed in the figure, will pafs on diverging as from a real object. Now if an eye be fituated at c, where Ac, Bc, rays proceeding from the extreme points of the object, make not a much larger angle AcB, than they would do if there were no lens interpofed, and the rays belonging to the fame pencil do not converge fo much as thofe the eye would receive if it were placed nearer to a or b, the object upon thefe accounts appearing very little larger or brighter than with the naked eye, is feen nearly in its proper place; but if the eye recedes a little way towards ab, the object then appearing both brighter and larger, feems to approach the lens: which is an evident proof of what has been fo often afferted, viz. that we judge of the diftance of an object in fome meafure by its brightnefs and magnitude; for the rays converge the more the farther the eye recedes from the lens; and therefore if we judged of the diftance of the object by the direction of the rays which flow from it, we ought in this cafe to conceive it at a greater diftance, than when the rays were parallel, or diverged at their entrance into the eye.

That the object fhould feem to approach the lens in this cafe, was a difficulty that exceedingly puzzled the learned Barrow, and which he pronounces infuperable, and not to be accounted for by any theory we have of vifion. Molineux alfo leaves it to the folution of others, as that which will be inexplicable, till a more intimate knowledge of the vifive faculty, as he expreffes it, be obtained by mortals.

They imagined, that feeing an object appears farther off, the lefs the rays diverge which fall upon the eye: if they fhould proceed parallel to each other, it ought to appear exceeding remote; and if they fhould converge, it fhould then appear more diftant ftill: the reafon of this was, becaufe they looked upon the apparent place of an object, as owing only to the direction of the rays whatever it was, and not at all to its apparent magnitude or fplendor.

Perhaps it may proceed from our judging of the diftance of an object in fome meafure by its magnitude, that that deception of fight commonly obferved by travellers may arife; viz. that upon the firft appearing of a building larger than ufual, as a cathedral church, or the like, it generally feems nearer to them, than they afterwards find it to be.

Prop. IV. If an object be placed farther from a convex lens than its focus of parallel rays, and the eye be fituated farther from it on the other fide than the place where the rays of the feveral pencils are collected into their refpective foci, the object appears inverted, and pendulous in the air, between the eye and the lens.

To explain this, let AB (fig. 6.) reprefent the object, CD the lens; and let the rays of the pencil ACD be collected in a, and thofe of BCD in b, forming there an inverted image of the object AB, and let the eye be placed in F: it is apparent from the figure, that fome of the refracted rays which pafs thro' each point of the image, will enter the eye as from a real object in that place; and therefore the object AB will appear there, as the propofition afferts. But we are fo little accuftomed to fee objects in this manner, that it is very difficult to perceive the image with one eye; but if both eyes are fituated in fuch a manner, that rays flowing from each point of the image may enter both, as at G and H, and we direct our optic axes to the image, it is eafy to be perceived.

If the eye be fituated in a or b, or very near them on either fide, the object appears exceedingly confufed, viz. if at d, the rays which proceed from the fame point of the object converge fo very much, and if at e, they diverge fo much, that they can-

Of Reflection.

not be collected together upon the retina, but fall upon it as if they were the axes of so many distinct pencils coming through every point of the lens; wherefore little more than one single point of the object is seen at a time, and that appears all over the lens; from whence nothing but confusion arises.

If the lens be so large that both eyes may be applied to it, as in *h* and *k*, the object will appear double; for it is evident from the figure, that the rays which enter the eye at *h* from either extremity of the object A or B, do not proceed as from the same point with that from whence those which enter the other at *k* seem to flow; the mind therefore is here deceived, and looks upon the object as situated in two different places, and therefore judges it to be double.

Prop. V. An object seen through a concave lens appears nearer, smaller, and less bright, than with the naked eye.

Plate CCXI.

Thus, let AB (fig. 7.) be the object, CD the pupil of an eye, and EF the lens. Now, as it is the property of a lens of this form, to render diverging rays more so, and converging ones less so, the diverging rays GH, GI, proceeding from the point G, will be made to diverge more, and so to enter the eye as from some nearer point *g*; and the rays AH, BI, which converge, will be made to converge less, and to enter the eye as from the points *a* and *b*; wherefore the object will appear in the situation *agb*, less and nearer than without the lens. Farther, as the rays which proceed from G are rendered more diverging, some of them will be made to pass by the pupil of the eye, which otherwise would have entered it, and therefore each point of the object will appear less bright.

Prop. VI. An object seen thro' a polygonous glass, that is, such as is terminated by several plain surfaces, is multiplied thereby.

For instance, let A (fig. 8.) be an object, and BC a polygonous glass terminated by the plain surfaces BD, DE, &c. and let the situation of the eye F be such, that the rays AB being refracted in passing thro' the glass, may enter it in the direction BF, and the rays AC in the direction CF. Then will the eye, by means of the former, see the object in G, and by the latter in H; and by means of the rays AI, the object will appear also in its proper situation A.

Sect. II. *Of the Reflection of Light.*

When a ray of light falls upon any body, however transparent, the whole of it never passes through the body, but some part is always driven back or reflected from it; and it is by this reflected light that all bodies which have no light of their own become visible to us. Of that part of the ray which enters, another part is also reflected from the second surface, or that which is farthest from the luminous body. When this part arrives again at the first surface, part of it is reflected back from that surface; and thus it continues to be reflected between the two surfaces, and to pass backwards and forwards within the substance of the medium, till some part is totally extinguished and lost. Besides this inconsiderable quantity, however, which is lost in this manner, the second surface often reflects much more than the first; insomuch that, in certain positions, scarce any rays will pass through both sides of the medium. A very considerable quantity is also unaccountably lost or extinguished at each reflecting surface; insomuch that no body, however transparent, can transmit all the rays which fall upon it; neither, tho' it be ever so well fitted for reflection, will it reflect them all.

§ 1. *Of the Cause of Reflection.*

The reflection of light is by no means so easily accounted for as the refraction of the same fluid. This property, as we have seen in the last section, may be accounted for in a satisfactory manner by the supposition of an attractive power diffused throughout the medium, and extending a very little way beyond it; but with regard to the reflection of light, there seems to be no satisfactory hypothesis hitherto invented. Of the principal opinions on this subject Mr Rowning hath given us the following account.

I. It was the opinion of philosophers before Sir Isaac Newton discovered the contrary, that light is reflected by impinging upon the solid parts of bodies. But that it is not so, is clear for the following reasons.

127 Light is not reflected by impinging on the solid parts of bodies at the first surface.

And first, it is not reflected at the first surface of a body by impinging against it.

For it is evident, that in order to the due and regular reflection of light, that is, that the reflected rays should not be dispersed and scattered one from another, there ought to be no rasures or unevenness in the reflecting surface large enough to bear a sensible proportion to the magnitude of a ray of light; because if the surface abounds with such, the reflected rays will rather be scattered like a parcel of pebbles thrown upon a rough pavement, than reflected with that regularity with which light is observed to be from a well-polished surface. Now those surfaces, which to our senses appear perfectly smooth and well polished, are far from being so; for to polish, is no other than to grind off the larger eminences and protuberances of the metal with the rough and sharp particles of sand, emery, or putty, which must of necessity leave behind them an infinity of rasures and scratches, which, tho' inconsiderable with regard to the former roughnesses, and too minute to be discerned by us, must nevertheless bear a large proportion to, if not vastly exceed, the magnitude of the particles of light.

128 Nor at the second.

Secondly, it is not reflected at the second surface, by impinging against any solid particles.

That it is not reflected by impinging upon the solid particles which constitute this second surface, is sufficiently clear from the foregoing argument; the second surfaces of bodies being as uncapable of a perfect polish as the first; and it is farther confirmed from hence, *viz.* that the quantity of light reflected differs according to the different density of the medium behind the body: And that it is not reflected by impinging upon the particles which constitute the surface of the medium behind it, is evident, because the strongest reflection of all at the second surface of a body, is when there is a vacuum behind it. This therefore wants no farther proof.

129 Supposition of a repulsive force.

II. It has been thought by some, that it is reflected at the first surface of a body, by a repulsive force equally diffused over it; and at the second, by an attractive force.

Of Reflection.

130 Objected to.

1. If there be a repulfive force diffufed over the furface of bodies that repels rays of light at all times, then, fince by increafing the obliquity of a ray we diminifh its perpendicular force (which is that only, whereby it muft make its way through this repulfive force), however weakly that force may be fuppofed to act, rays of light may be made to fall with fo great a degree of obliquity on the reflecting furface, that there fhall be a total reflection of them there, and not one particle of light be able to make its way through: which is contrary to obfervation; the reflection of light at the firft furface of a tranfparent body being never total in any obliquity whatever. The hypothefis therefore in this particular muft be falfe.

131 Attractive force fuppofed.

2. As to the reflection at the fecond furface by the attractive force of the body; this may be confidered in two refpects: firft, when the reflection is total; fecondly, when it is partial.

And firft, in cafes where the reflection is total, the caufe of it is undoubtedly that fame attractive force by which light would be refracted in paffing out of the fame body. This is manifeft from that analogy which is obfervable between the reflection of light at this fecond furface, and its refraction there. For otherwife, what can be the reafon that the total reflection fhould begin juft when the obliquity of the incident ray, at its arrival at the fecond furface, is fuch, that the refracted angle ought to be a right one; or when the ray, were it not to return in reflection, ought to pafs on parallel to the furface, without going from it? For in this cafe it is evident, that it ought to be returned by this very power, and in fuch manner that the angle of reflection fhall be equal to the angle of incidence: juft as a ftone thrown obliquely from the earth, after it is fo far turned out of its courfe by the attraction of the earth, as to begin to move horizontally, or parallel to the furface of the earth, is then by the fame power made to return in a curve fimilar to that which is defcribed in its departure from the earth, and fo falls with the fame degree of obliquity that it was thrown with.

But fecondly, as to the reflection at the fecond furface, when it is partial; an attractive force uniformly fpread over it, as the maintainers of this hypothefis conceive it to be, can never be the caufe thereof. Becaufe it is inconceivable, that the fame force, acting in the fame circumftances in every refpect, can fometimes reflect the violet coloured rays and tranfmit the red, and at other times reflect the red and tranfmit the violet.

This argument concludes equally againft a repulfive force uniformly diffufed over the firft furface of a body, and reflecting light there; becaufe fome bodies reflect the violet and tranfmit the red, others reflect the red and tranfmit the violet, at their firft furface; which cannot poffibly be upon this fuppofition, the rays of whichever of thefe colours we fuppofe to be the ftrongeft.

132 Another ypothefis.

III. Some, being apprehenfive of the infufficiency of a repulfive and attractive force diffufed over the furfaces of bodies and acting uniformly, have fuppofed, that, by the action of light upon the furface of bodies, the matter of thefe forces is put into an undulatory motion; and that where the furface of it is fubfiding light is tranfmitted, and in thofe places where it is rifing light is reflected. But this feems not to advance us one jot farther; for in thofe cafes, fuppofe where red is reflected and violet tranfmitted, how comes it to pafs that the red impinges only on thofe parts when the waves are rifing, and the violet when they are fubfiding?

133 Sir Ifaac Newton's hypothefis.

IV. The next hypothefis that we fhall take notice of, is that remarkable one of Sir Ifaac Newton's fits of eafy reflection and tranfmiffion, which we fhall now explain and examine.

That author, as far as we can apprehend his meaning in this particular, is of opinion, that light, in its paffage from the luminous body, is difpofed to be alternately reflected by and tranfmitted through any refracting furface it may meet with; that thefe difpofitions (which he calls *fits of eafy reflection and eafy tranfmiffion)* return fucceffively at equal intervals: and that they are communicated to it at its firft emiffion out of the luminous body it proceeds from, probably by fome very fubtle and elaftic fubftance diffufed through the univerfe, and that in the following manner. As bodies falling into water, or paffing through the air, caufe undulations in each, fo the rays of light may excite vibrations in this elaftic fubftance. The quicknefs of which vibrations depending on the elafticity of the medium (as the quicknefs of the vibrations in the air, which propagate found, depend folely on the elafticity of the air, and not upon the quicknefs of thofe in the founding body) the motion of the particles of it may be quicker than that of the rays: and therefore, when a ray at the inftant it impinges upon any furface, is in that part of a vibration of this elaftic fubftance which confpires with its motion, it it may be eafily tranfmitted; and when it is in that part of a vibration which is contrary to its motion, it may be reflected. He farther fuppofes, that when light falls upon the firft furface of a body, none is reflected there; but all that happens to it there is, that every ray that is not in a fit of eafy tranfmiffion is there put into one, fo that when they come at the other fide (for this elaftic fubftance, eafily pervading the pores of bodies, is capable of the fame vibrations within the body as without it) the rays of one colour fhall be in a fit of eafy tranfmiffion, and thofe of another in a fit of eafy reflection, according to the thicknefs of the body, the intervals of the fits being different in rays of a different kind. This very well accounts for the different colours of the bubble and thin plate of air and water, as is obvious enough; and likewife for the reflection of light at the fecond furface of a thicker body; for the light reflected from thence is alfo obferved to be coloured, and to form rings according to the different thicknefs of the body, when not intermixed and confounded with other light, as will appear from the following experiment. If a piece of glafs be ground concave on one fide and convex on the other, both its concavity and convexity having one common centre; and if a ray of light be made to pafs through a fmall hole in a piece of paper held in that common centre, and be permitted to fall on the glafs; befides thofe rays which are regularly reflected back to the hole again, there will be others reflected to the paper, and form coloured rings furrounding the hole, not unlike thofe occafioned by the reflection of light from thin plates.

The fame will happen if the rays be reflected from a metalline fpeculum, but the light will not be coloured; which fhews, that the colours arife from that light which is reflected from the back-fide, and that in the following manner: Befides that light which is regularly reflected from the farther furface of the glafs, there is fome reflected irregularly, which, paffing from the back furface under the different obliquities, does as it were pafs through glaffes of different thickneffes, and therefore is in part reflected back again when it comes to the firft furface, and is in part tranfmitted through it, the tranfmited light, when received upon the white paper, exhibiting the rings of colours abovementioned.

As to the light which is fuppofed to be reflected at the firft furface, his opinion feems to be, That it is not there reflected, but that it really enters the furface, and is reflected from the back-fide of the firft feries of particles that lie therein: fo that, according as thefe particles are larger or fmaller, the rays of light which at their entrance into them (for they are tranfparent, whether the body they compofe be fo or not) are thereby put into fits of eafy tranfmiffion, at their emerfion at the other fide are fome in a fit of eafy tranfmiffion, others in a fit of eafy reflection, according as the interval of their fits are large or fmall. So that the particles of a body may be of fuch a fize that they fhall reflect the red and tranfmit the violet, or that they may reflect the violet and tranfmit the red; or, in general, that the ftrongeft and moft forcible rays may be tranfmitted while the weaker are reflected; or the weaker may be tranfmitted while the ftronger are reflected.

§. 2. *Of the Laws of Reflection.*

The fundamental law of the reflection of light is, that in all cafes the angle of reflection is equal to the angle of incidence. This is found by experiment to be the cafe, and befides may be demonftrated mathematically from the laws of percuffion in bodies perfectly elaftic. The axiom therefore holds good in every cafe of reflection, whether it be from plain furfaces or fpherical ones, and that whether they are convex or concave; and hence the feven following propofitions relating to the reflection of light from plain and fpherical furfaces may be deduced.

I. Rays of light reflected from a plain furface have the fame degree of inclination to one another that their refpective incident ones have.—For the angle of reflection of each ray being equal to that of its refpective incident one, it is evident, that each reflected ray will have the fame degree of inclination to that portion of the furface from whence it is reflected that its incident one has: but it is here fuppofed, that all thofe portions of furface from whence the rays are reflected, are fituated in the fame plain; confequently the reflected rays will have the fame degree of inclination to each other that their incident ones have, from whatever part of the furface they are reflected.

II. Parallel rays reflected from a concave furface are rendered converging.—To illuftrate this, let AF, CD, EB, (fig. 1.) reprefent three parallel rays falling upon the concave furface FB, whofe centre is C. To the points F and B draw the lines CF, CB; thefe being drawn from the centre, will be perpendicular to the furface at thofe points. The incident ray CD alfo paffing through the centre, will be perpendicular to the furface, and therefore will return after reflection in the fame line; but the oblique rays AF and EB will be reflected into the lines FM and BM, fituated on the contrary fide of their refpective perpendiculars CF and CB. They will therefore proceed converging after reflection towards fome point, as M, in the line CD.

Plate CCXII.

III. Converging rays falling on the like furface, are made to converge more.—For, every thing remaining as above, let GF, HB, be the incident rays. Now, becaufe thefe rays have larger angles of incidence than the parallel ones AF and EB in the foregoing cafe, their angles of reflection will alfo be larger than thofe of the others; they will therefore converge after reflection, fuppofe in the lines FN and BN, having their point of concourfe N farther from the point C than M, that to which the parallel rays AF and EB converged to in the foregoing cafe; and their precife degree of convergency will be greater than that wherein they converged before reflection.

IV. Diverging rays falling upon the like furface, are, after reflection, parallel, diverging, or converging. If they diverge from the focus of parallel rays, they then become parallel; if from a point nearer to the furface than that, they will diverge, but in a lefs degree than before reflection; if from a point between that and the centre, they will converge after reflection, and that to fome point on the contrary fide of the centre, but fituated farther from it than the point from which they diverged. If the incident rays diverge from a point beyond the centre, the reflected ones will converge to one on the other fide of it, but nearer to it than the point they diverged from; and if they diverge from the centre, they will be reflected thither again.

1. Let them diverge in the lines MF, MB, proceeding from M, the focus of parallel rays; then, as the parallel rays AF and EB were reflected into the lines FM and BM, (by Prop. II.) thefe rays will now on the contrary be reflected into them.

2. Let them diverge from N, a point nearer to the furface than the focus of parallel rays, they will then be reflected into the diverging lines FG and BH, which the incident rays GF and HB defcribed that were fhewn to be reflected into them in the foregoing propofition; but the degree wherein they diverge will be lefs than that wherein they diverged before reflection.

3. Let them proceed diverging from X, a point between the focus of parallel rays and the centre; they then make lefs angles of incidence than the rays MF and MB, which became parallel by reflection: they will confequently have lefs angles of reflection, and proceed therefore converging towards fome point, as Y; which point will always fall on the contrary fide of the centre, becaufe a reflected ray always falls on the contrary fide of the perpendicular with refpect to that on which its incident one falls; and of confequence it will be farther diftant from the centre than X.

4. If the incident ones diverge from Y, they will, after reflection, converge to X; thofe which were the incident rays in the former cafe being the reflected ones

Plate CCXII.

ones in this. And, laftly,

5. If the incident rays proceed from the centre, they fall in with their refpective perpendiculars; and for that reafon are reflected thither again.

V. Parallel rays reflected from a convex furface, are rendered diverging.—For, let AB, GD, EF, (fig. 2.) be three parallel rays falling upon the convex furface BF, whofe centre of convexity is C, and let one of them, viz. GD, be perpendicular to the furface. Through B, D, and F, the points of reflection, draw the lines CV, CG, and CT; which, becaufe they pafs through the centre, will be perpendicular to the furface at thefe points. The incident ray GD being perpendicular to the furface, will return after reflection in the fame line, but the oblique ones AB and EF in the lines BK and FL fituated on the contrary fide of their refpective perpendiculars BV and FT. They will therefore diverge, after reflection, as from fome point M in the line GD produced; and this point will be in the middle between D and C.

VI. Diverging rays reflected from the like furface, are rendered more diverging.—For, every thing remaining as above, let GB, GF, be the incident rays. Thefe having larger angles of incidence than the parallel ones AB and EF in the preceding cafe, their angles of reflection will alfo be larger than theirs: they will therefore diverge after reflection, fuppofe in the lines BP and FQ, as from fome point N, farther from C than the point M; and the degree wherein they will diverge will be greater than that wherein they diverged before reflection.

VII. Converging rays reflected from the like furface, are parallel, converging, or diverging. If they tend towards the focus of parallel rays, they then become parallel; if to a point nearer the furface than that, they converge, but in a lefs degree than before reflection; if to a point between that and the centre, they will diverge after reflection, as from fome point on the contrary fide of the centre, but fituated farther from it than the point they converged to: if the incident rays converge to a point beyond the centre, the reflected ones will diverge as from one on the contrary fide of it, but nearer to it than the point to which the incident ones converged; and if the incident rays converge towards the centre, the reflected ones will proceed as from thence.

1. Let them converge in the lines KB and LF, tending towards M, the focus of parallel rays; then, as the parallel rays AB EF were reflected into the lines BK and FL (by Prop. V.), thofe rays will now on the contrary be reflected into them.

2. Let them converge in the lines PB, QF, tending towards N a point nearer the furface than the focus of parallel rays, they will then be reflected into the converging lines BG and FG, in which the rays GB GF proceeded that were fhewn to be reflected into them by the laft propofition: but the degree wherein they will converge will be lefs than that wherein they converged before reflection.

3. Let them converge in the lines RB and SF proceeding towards X, a point between the focus of parallel rays and the centre; their angles of incidence will then be lefs than thofe of the rays KB and LF, which became parallel after reflection: their angles of reflection will therefore be lefs; on which account they muft neceffarily diverge, fuppofe in the lines BH and FI, from fome point, as Y; which point, (by Prop. IV.) will fall on the contrary fide of the centre with refpect to X, and will be farther from it than that.

4. If the incident rays tend towards Y, the reflected ones will diverge as from X; thofe which were the incident ones in one cafe, being the reflected ones in the other.

5. Laftly, if the incident rays converge towards the centre, they fall in with their refpective perpendiculars; on which account they proceed after reflection as from the centre.

We have already obferved, that in fome cafes there is a very great reflection from the fecond furface of a tranfparent body. The degree of inclination neceffary to caufe a total reflection of a ray at the fecond furface of a medium, is that which requires that the refracted angle (fuppofing the ray to pafs out there) fhould be equal to or greater than a right one; and confequently it depends on the refractive power of the medium through which the ray paffes, and is therefore different in different media. When a ray paffes through glafs furrounded with air, and is inclined to its fecond furface under an angle of 42 degrees or more, it will be wholly reflected there. For, as 11 is to 17, (the ratio of refraction out of glafs into air), fo is the fine of an angle of 42 degrees to a fourth number, that will exceed the fine of a right angle. From hence it follows, that when a ray of light arrives at the fecond furface of a tranfparent fubftance with as great, or a greater degree of obliquity, than that which is neceffary to make a total reflection, it will there be all returned back to the firft; and if it proceeds towards that with as great an obliquity as it did towards the other, (which it will do if the furfaces of the medium be parallel to each other), it will there be all reflected again, &c. and will therefore never get out, but pafs from fide to fide, till it be wholly fuffocated and loft within the body.—From hence may arife an obvious inquiry, how it comes to pafs, that light falling very obliquely upon a glafs widow from without, fhould be tranfmitted into the room? In anfwer to this it muft be confidered, that however obliquely a ray falls upon the furface of any medium whofe fides are parallel, (as thofe of the glafs in a window are), it will fuffer fuch a degree of refraction in entering there, that it fhall fall upon the fecond with a lefs obliquity than that which is neceffary to caufe a total reflection. For inftance, let the medium be glafs, as fuppofed in the prefent cafe; then, as 17 is to 11, (the ratio of refraction out of air into glafs), fo is the fine of the largeft angle of incidence with which a ray can fall upon any furface to the fine of a lefs angle than that of total reflection. And therefore, if the fides of the glafs be parallel, the obliquity with which a ray falls upon the firft furface, cannot be fo great, but that it fhall pafs the fecond without fuffering a total reflecton there.

When light paffes out of a denfer into a rarer medium, the nearer the fecond medium approaches the firft in denfity (or more properly in its refractive power), the lefs of it will be refracted in paffing from one to the other; and when their refracting powers are equal,

Of Reflection.

equal, all of it will paſs into the ſecond medium.

The above propoſitions may be all mathematically demonſtrated in the following manner.

Prop. I. Of the reflection of rays from a plain ſurface.

"When rays fall upon a plain ſurface, if they diverge, the focus of the reflected rays will be at the ſame diſtance behind the ſurface, that the radiant point is before it: if they converge, it will be at the ſame diſtance before the ſurface, that the imaginary focus of the incident rays is behind it."

This propoſition admits of two caſes.

Case 1. Of diverging rays.

Plate CCXII.

Dem. Let AB, AC, (fig. 3.) be two diverging rays incident on the plain ſurface DE, the one perpendicularly, the other obliquely: the perpendicular one AB will be reflected to A, proceeding as from ſome point in the line AB produced; the oblique one AC will be reflected into ſome line as CF, ſuch that the point G, where the line FG produced interſects the line AB produced alſo, ſhall be at an equal diſtance from the ſurface DE with the radiant A. For the perpendicular CH being drawn, ACH and HCF will be the angles of incidence and reflection; which being equal, their complements ACB and FCE are ſo too: but the angle BCG is equal to FCE, as being vertical to it: therefore in the triangles ABC and GBC the angles at C are equal, the ſide BC is common, and the angles at B are alſo equal to each other, as being right ones; therefore the lines AB and BG, which reſpect the equal angles at C, are alſo equal; and conſequently the point G, the focus of the incidents rays AB, AC, is at the ſame diſtance behind the ſurface, that the point A is before it. *Q. E. D.*

Case 2. Of converging rays.

This is the converſe of the former caſe. For ſuppoſing FC and AB to be two converging incident rays, CA and BA will be the reflected ones (the angles of incidence in the former caſe being now the angles of reflection, and *vice verſa*), having the point A from their focus; but this, from what was demonſtrated above, is at an equal diſtance from the reflecting ſurface with the point G, which in this caſe is the imaginary focus of the incident rays, FC, and AB.

Obs. It is not here, as in the refraction of rays in paſſing through a plain ſurface, where ſome of the refracted rays proceed as from one point, and ſome as from another: but they all proceed after reflection as from one and the ſame point, however obliquely they may fall upon the ſurface; for what is here demonſtrated of the ray AC holds equally of any other, as AI, AK, &c.

The caſe of parallel rays incident on a plain ſurface, is included in this propoſition: for in that caſe we are to ſuppoſe the radiant to be at an infinite diſtance from the ſurface, and then by the propoſition the focus of the reflected rays will be ſo too; that is, the rays will be parallel after reflection, as they were before.

Prop. II. Of the reflection of parallel rays from a ſpherical ſurface.

"When parallel rays are incident upon a ſpherical ſurface, the focus of the reflected rays will be the middle point between the centre of convexity and the ſurface."

This propoſition admits of two caſes.

Case 1. Of parallel rays falling upon a convex ſurface.

Dem. Let AB, DH, (fig. 4.) repreſent two parallel rays incident on the convex ſurface BH, the one perpendicularly, the other obliquely; and let C be the centre of convexity; ſuppoſe HE to be the reflected ray of the oblique incident one DH proceeding as from F, a point in the line AB produced. Through the point H draw the line CI, which will be perpendicular to the ſurface at that point; and the angles DHI and IHF, being the angles of incidence and reflection, will be equal. To the former of theſe, the angle HCF is equal, the lines AC and DH being parallel, and to the latter the angle CAF as being vertical; wherefore the triangle CFH is iſoſceles, and conſequently the ſides CF and FH are equal: but ſuppoſing BH to vaniſh, FH is equal to FB; and therefore upon this ſuppoſition FC and FB are equal, that is, the focus of the reflected rays is the middle point between the centre of convexity and the ſurface. *Q. E. D.*

Case 2. Of parallel rays falling upon a concave ſurface.

Dem. Let AB, DH (fig. 5.) be two parallel rays incident, the one perpendicularly, the other obliquely, on the concave ſurface BH, whoſe centre of concavity is C. Let BF and HF be the reflected rays meeting each other in F; this will be the middle point between B and C. For drawing through C the perpendicular CH, the angles DHC and FHC, being the angles of incidence and reflection, will be equal, to the former of which the angle HCF is equal, as alternate; and therefore the triangle CFH is iſoſceles. Wherefore CF and FH are equal: but if we ſuppoſe BH to vaniſh, FB and FH are alſo equal, and therefore CF is equal to FB; that is, the focal diſtance of the reflected rays is the middle point between the centre and the ſurface. *Q. E. D.*

Obs. It is here obſervable, that the farther the line DH, either in fig. 4. or 5. is taken from AB, the nearer the point F falls to the ſurface. For the farther the point H recedes from B, the larger the triangle CFH will become; and conſequently, ſince it is always an iſoſceles one, and the baſe CH, being the radius, is every where of the ſame length, the equal legs CF and FH will lengthen; but CF cannot grow longer unleſs the point F approach towards the ſurface. And the farther H is removed from B, the faſter F approaches to it.

This is the reaſon, that whenever parallel rays are conſidered as reflected from a ſpherical ſurface, the diſtance of the oblique one from the perpendicular one is taken ſo ſmall with reſpect to the focal diſtance of that ſurface, that without any phyſical error it may be ſuppoſed to vaniſh.

From hence it follows, that if a number of parallel rays, as AB, CD, EG, &c. fall upon a convex ſurface, (as fig. 6.) and if BA, DK, the reflected rays of the incident ones AB, CD, proceed as from the point F, thoſe of the incident ones CD, EG, viz. DK, GL, will proceed as from N, thoſe of the incident ones EG, HI, as from O, &c. becauſe the farther the incident ones CD, EG, &c. are from AB, the nearer to the ſurface are the points F, *f*, *f*, in the line BF, from which they proceed after reflection; ſo that properly the foci of the reflected rays BA, DK, GL, &c. are not

Of Reflection.

not in the line AB produced, but in a curve line passing thro' the points F, N, O, &c.

The same is applicable to the case of parallel rays reflected from a concave surface, as expressed by the pricked lines on the other half of the figure, where PQ, RS, TV, are the incident rays; QF, S*f*, V*f*, the reflected ones, intersecting each other in the points X, Y, and F; so that the foci of those rays are not in the line FB, but in a curve passing through those points.

Plate CCXII.

Had the surface BH in fig. 4. or 5. been formed by the revolution of a parabola about its axis having its focus in the point F, all the rays reflected from the convex surface would have proceeded as from the point F, and those reflected from the concave would have fallen upon it, however distant their incident ones AB, DH, might have been from each other. For in the parabola, all lines drawn parallel to the axis make angles with the tangents to the points where they cut the parabola (that is, with the surface of the parabola) equal to those which are made with the same tangents by lines drawn from thence to the focus; therefore, if the incident rays describe those parallel lines, the reflected ones will necessarily describe these other, and so will all proceed as from, or meet in, the same point.

Prop. III. Of the reflection of diverging and converging rays from a spherical surface.

" When rays fall upon any spherical surface, if they diverge, the distance of the focus of the reflected rays from the surface is to the distance of the radiant point from the same (or, if they converge, to that of the imaginary focus of the incident rays), as the distance of the focus of the reflected rays from the centre is to the distance of the radiant point (or imaginary focus of the incident rays) from the same."

This proposition admits of ten cases.

Case 1. Of diverging rays falling upon a convex surface.

Dem. Let RB, RD (fig. 7.) represent two diverging rays flowing from the point R as from a radiant, and falling the one perpendicularly, the other obliquely, on the convex surface BD, whose centre is C. Let DE be the reflected ray of the incident one RD, produce ED to F, and through R draw the line RH parallel to FE till it meets CD produced in H. Then will the angle RHD be equal to EDH the angle of reflection, as being alternate to it, and therefore equal also to RDH which is the angle of incidence; wherefore the triangle DRH is isosceles, and consequently DR is equal to RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are similar, (or to express it in Euclid's way, the sides of the triangle RHC are cut proportionably, 2 Elem. 6.): and therefore FD is to RH, or its equal RD, as CF to CR; but BD vanishing, FD and RD differ not from FB and RB: wherefore FB is to RB also, as CF to CR; that is, the distance of the focus from the surface is to the distance of the radiant point from the same, as the distance of the focus from the centre is to the distance of the radiant from thence. *Q. E. D.*

Case 2. Of converging rays falling upon a concave surface.

Dem. Let KD and CB be the converging incident rays having their imaginary focus in the point R, which was the radiant in the foregoing case. Then as RD was in that case reflected into DE, KD will in this be reflected into DF; for, since the angles of incidence in both cases are equal, as they are by being vertical, the angles of reflection will be so too; so that F will be the focus of the reflected rays: but it was there demonstrated, that FB is to RB as CF to CR; that is, the distance of the focus from the surface is to the distance (in this Case) of the imaginary focus of the incident rays, as the distance of the focus from the centre is the distance of the imaginary focus of the incident rays from the same. *Q. E. D.*

Case 3. Of converging rays falling upon a convex surface, and tending to a point between the focus of parallel rays and the centre.

Dem. Let BD (fig. 8.) represent a convex surface whose centre is C, and whose focus of parallel rays is P; and let AB, KD, be two converging rays incident upon it, and having their imaginary focus at R, a point between P and C. Now because KD tends to a point between the focus of parallel rays and the centre, the reflected ray DE will diverge from some point on the other side the centre, suppose F; as explained above (p. 5547.) under prop. 7. Through D draw the perpendicular CD, and produce it to H; then will KDH and HDE be the angles of incidence and reflection, which being equal, their vertical ones RDC and CDF will be so too, and therefore the vertex of the triangle RDF is bisected by the line DC: wherefore (3 El. 6.) FD and DR or BD vanishing, FB and BR are to each other as FC to CR; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident ones, as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

Case 4. Of diverging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the centre.

Dem. Let RB, RD, be the diverging rays incident upon the concave surface BD, having their radiant point in the point R, the imaginary focus of the incident rays in the foregoing case. Then as KD was in that case reflected into DE, RD will now be reflected into DF. But it was there demonstrated, that FB and RB are to each other, as CF to CR; that is, the distance of the focus is to that of the radiant, as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

The angles of incidence and reflection being equal, it is evident, that if, in any case, the reflected ray be made the incident one, the incident will become the reflected one: and therefore the four following cases may be considered respectively as the converse of the four foregoing; for in each of them the incident rays are supposed to coincide with the reflected ones in the other. Or they may be demonstrated independently of them as follows.

Case 5. Of converging rays falling upon a convex surface, and tending to a point nearer the surface than the focus of parallel rays.

Dem. Let ED, RB (fig. 7.) be the converging rays incident upon the convex surface BD whose centre

Of Reflection.

tre is C, and focus of parallel rays is at P; and let the imaginary focus of the incident rays be at F, a point between P and B; and let DR be the reflected ray. From C and R draw the lines CH, RH, the one passing through D, the other parallel to FE. Then will the angle RHD be equal to HDE the angle of incidence, as alternate to it; and therefore equal to HDR, the angle of reflection: wherefore the triangle HDR is isosceles, and consequently DR is equal to RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are similar; and therefore RH, or RD, is to FD as CR to CF: but BD vanishing, RD and FD coincide with RB and FB, wherefore RB is to FB as CR to CF; that is, the distance of the focus from the surface is to the distance of the imaginary focus of the incident rays, as the distance of the focus from the centre is to the distance of the imaginary focus of the incident rays from the same. *Q. E. D.*

Case 6. Of diverging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the surface.

Dem. Let FD and FB represent two diverging rays flowing from the point F as a radiant, which was the imaginary focus of the incident rays in the foregoing case. Then as ED was in that case reflected into DR, FD will be reflected into DK, (for the reason mentioned in Case the second), so that the reflected ray will proceed as from the point R: but it was demonstrated in the case immediately foregoing, that RB is to FB as CR to CF; that is, the distance of the focus from the surface is to that of the radiant from the same, as the distance of the former from the centre is to that of the latter from the same. *Q. E. D.*

Case 7. Of converging rays falling upon a convex surface, and tending towards a point beyond the centre.

Plate CCXII.

Dem. Let AB, ED, (fig. 8.) be the incident rays tending to F, a point beyond the centre C, and let DK be the reflected ray of the incident one ED. Then because the incident ray ED tends to a point beyond the centre, the reflected ray DK will proceed as from one on the contrary side, suppose R; as explained above under Prop. VII. Through D draw the perpendicular CD, and produce it to H. Then will EDH and HDK be the angles of incidence and reflection; which being equal, their vertical ones CDF and CDR will be so too: consequently the vertex of the triangle FDR is bisected by the line CD: wherefore, RD is to DF, or (3 Elem. 6.) BD vanishing, RB is to BF as RC to CF; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident rays, as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

Case 8. Of diverging rays falling upon a concave surface, and proceeding from a point beyond the centre.

Dem. Let FB, FD, be the incident rays having their radiant in F, the imaginary focus of the incident rays in the foregoing case. Then as ED was in that case reflected into DK, FD will now be reflected into DR; so that R will be the focus of the reflected rays. But it was demonstrated in the foregoing case, that RB is to FB as RC to CF; that is, the distance of the focus of the reflected rays from the surface is to the distance of the radiant from the same, as the distance of the focus of the reflected rays from the centre is to the distance of the radiant from thence. *Q. E. D.*

The two remaining cases may be considered as the converse of those under Prop. II. (p. 5548.), because the incident rays in these are the reflected ones in them; or they may be demonstrated in the same manner with the foregoing, as follows.

Case 9. Converging rays falling upon a convex surface, and tending to the surface of parallel rays, become parallel after reflection.

Dem. Let ED, RB, (fig. 7.) represent two converging rays incident on the convex surface BD, and tending towards F, which we will now suppose to be the focus of parallel rays; and let DR be the reflected ray, and C the centre of convexity of the reflecting surface. Through C draw the line CD, and produce it to H, drawing RH parallel to ED produced to F. Now it has been demonstrated (Case 5.) where the incident rays are supposed to tend to the point F, that RB is to FB as RC to CF; but F in this Case being supposed to be the focus of parallel rays, it is the middle point between C and B (by proposition 2d), and therefore FB and FC are equal; and consequently the two other terms in the proportion, viz. RB and RC, must be so too; which can only be upon a supposition that R is at an infinite distance from B; that is, that the reflected rays BR and DR be parallel. *Q. E. D.*

Case 10. Diverging rays falling upon a concave surface, and proceeding from the focus of parallel rays, become parallel after reflection.

Dem. Let RD, RB (fig. 8.) be two diverging rays incident upon the concave surface BD, as supposed in Case 4.; where it was demonstrated that FB is to RB as CF to CR. But in the present case RB and CR are equal, because R is supposed to be the focus of parallel rays; therefore FB and FC are so too. Which cannot be unless F be taken at an infinite distance from B; that is, unless the reflected rays BF and DF be parallel. *Q. E. D.*

Obs. It is here observable, that in the case of diverging rays falling upon a convex surface, (see fig. 7.) the farther the point D is taken from B, the nearer the point F, the focus of the reflected rays, approaches to B, while the radiant R remains the same. For it is evident from the curvature of a circle, that the point D (fig. 9.) may be taken so far from B, that the reflected ray DE shall proceed as from F, G, H, or even from B, or from any point between B and R; and the farther it is taken from B, the faster the point from which it proceeds, approaches towards R: as will easily appear if we draw several incident rays with their respective reflected ones, in such manner that the angles of reflection may be all equal to their respective angles of incidence, as is done in the figure. The like is applicable to any of the other cases of diverging or converging rays incident upon a spherical surface. This is the reason, that when rays are considered as reflected from a spherical surface, the distance of the oblique rays from the perpendicular one is taken so small, that it may be supposed to vanish.

From

Of Reflection.

From hence it follows, that if a number of diverging rays are incident upon the convex surface BD at the several points B, D, D, &c. they shall not proceed after reflection as from any point in the line RB produced, but as from a curve line passing thro' the several points F, *f*, *f*, &c. The same is applicable in all the other cases.

Plate CCXII.

Had the curvature BD (fig. 7.) been hyperbolical, having its foci in R and F; then R being the radiant, (or the imaginary focus of incident rays), F would have been the focus of the reflected ones, and *vice versa*, however distant the points B and D might be taken from each other. In like manner, had the curve BD (fig. 8.) been elliptical, having its foci in F and R, the one of these being made the radiant (or imaginary focus of incident rays), the other would have been the focus of reflected ones, and *vice versa*. For both in the hyperbola and ellipsis, lines drawn from each of their foci through any point make equal angles with the tangent to that point. Therefore, if the incident rays proceed to or from one of their foci, the reflected ones will all proceed as from or to the other. So that, in order that diverging or converging rays may be accurately reflected to or from a point, the reflecting surface must be formed by the revolution of an hyperbola about its longer axis, when the incident rays are such, that their radiant, or imaginary focus of incident rays, shall fall on one side the surface, and the focus of the reflected ones on the other: when they are both to fall on the same side, it must be formed by the revolution of an ellipsis about its longer axis. However, upon account of the great facility with which spherical surfaces are formed in comparison of that with which surfaces formed by the revolution of any of the conic sections about their axes are made, the latter are very rarely used. Add to this another inconvenience, *viz.* that the foci of these curves being mathematical points, it is but one point of the surface of an object that can be placed in any of them at a time, so that it is only in theory that surfaces formed by the revolution of these curves about their axes render reflection perfect.

Now, because the focal distance of rays reflected from a spherical surface cannot be found by the analogy laid down in the third proposition, without making use of the quantity sought; we shall here give an instance whereby the method of doing it in all others will readily appear.

Prob. Let it be required to find the focal distance of diverging rays incident upon a convex surface, whose radius of convexity is 5 parts, and the distance of the radiant from the surface is 20.

Sol. Call the focal distance sought x; then will the distance of the focus from the centre be $5-x$, and that of the radiant from the same 25: therefore by prop. 3. we have the following proportion, *viz.* $x : 20 :: 5-x : 25$; and multiplying extremes together and means together, we have $25x = 100-20x$, which, after due reduction, gives $x=\frac{100}{45}$.

If in any case it should happen that the value of x should be a negative quantity, the focal point must then be taken on the contrary side the surface to that on which it was supposed that it would fall in stating the problem.

If letters instead of figures had been made use of in the foregoing solution, a general theorem might have been raised, to have determined the focal distance of reflected rays in all cases whatever. See this done in Suppl. to *Gregory's Optics*, 2d edit. p. 112.

Because it was, in the preceding section, observed, that different incident rays, though tending to or from one point, would after refraction proceed to or from different points, a method was there inserted of determining the distinct point, which each separate ray entering a spherical surface converges to, or diverges from, after refraction: the same has been observed here with regard to rays reflected from a spherical surface, (see obs. in case 2. and case 10.) But the method of determining the distinct point to or from which any given incident ray proceeds after reflection, is much more simple. It is only necessary to draw the reflected ray such, that the angle of reflection may be equal to the angle of incidence, which will determine the point it proceeds to or from in any case whatever.

§ 3. *Of the Appearance of Bodies seen by Light reflected from plane and spherical Surfaces.*

Whatever hath been said concerning the appearance of bodies seen by refracted light through lenses, respects also the appearance of bodies seen by reflection. But besides these, there is one thing peculiar to images by reflection, *viz.* that each point in the representation of an object made by reflection appears situated somewhere in an infinite right line that passes through its correspondent point in the object, and is perpendicular to the reflecting surface.

The truth of this appears sufficiently from the propositions formerly laid down; in each of which, rays flowing from any radiant point, are shewn to proceed, after reflection, to or from some point in a line that passes through the said radiant, and is perpendicular to the reflecting surface. For instance, (fig. 1.) rays flowing from Y are collected in X, a point in the perpendicular CD, which, being produced, passes through Y; again, (fig. 2.) rays flowing from from G, proceed, after reflection, as from N, a point in the perpendicular CD, which, being produced, passes thro' G; and so of the rest.

Plate CCXII.

This observation, however, except where an object is seen by reflection from a plain surface, relates only to those cases where the representation is made by means of such rays as fall upon the reflecting surface with a very small degree of obliquity; because such as fall at a considerable distance from the perpendicular, proceed not after reflection as from any point in that perpendicular, but as from other points situated in a certain curve, as hath already been explained; upon which account these rays are neglected, as making a confused and deformed representation. And therefore it is to be remembered, that however the situation of the eye with respect to the object and reflecting surface may be represented in the following figures, it is to be supposed as situated in such a manner with respect to the object, that rays flowing from thence and entering it after reflection, may be such only as fall with a very small degree of obliquity upon the surface; that is, the eye must be supposed to be placed almost directly behind the object, or between it and the reflecting surface. The reason why it is not always so placed, is only to avoid confusion in the figures.

Of Reflection.

I. When an object is seen by reflection from a plane surface, the image of it appears at the same distance behind the surface that the object is placed before it, of the same magnitude therewith, and directly opposite to it.

Plate CCXII.

To explain this, let AB (fig. 10.) represent an object seen by reflection from the plain surface SV; and let the rays AF, AG, be so inclined to the surface, that they shall enter an eye at H after reflection; and let AE be perpendicular to the surface: then, by the observation just mentioned, the point A will appear in some part of the line AE produced; suppose I, that is, the oblique rays AF and AG will proceed after reflection as from that point; and further, because the reflected rays FH, GK, will have the same degree of inclination to one another that their incident ones have, that point must necessarily be at the same distance from the surface that the point A is; the representation therefore of the point A, will be at the same distance behind the surface that the point itself is before it, and directly opposite to it: consequently, since the like may be shewn of the point B, or of any other, the whole image IM will appear at the same distance behind the surface that the object is before it, and directly opposite to it; and because the lines AI, BM, which are perpendicular to the plain surface, are for that reason parallel to each other, it will also be of the same magnitude therewith.

II. When an object is seen by reflection from a convex surface, its image appears nearer to the surface, and less than the object.

Let AB (fig. 12.) represent the object, SV a reflecting surface whose centre of convexity is C: and let the rays AF, AG, be so inclined to the surface, that after reflection thereat they shall enter the eye at H: and let AE be perpendicular to the surface: then will the oblique rays AF, AG, proceed after reflection as from some point in the line AE produced, suppose from I; which point, because the reflected rays will diverge more than the incident ones, must be nearer to the surface than the point A. And since the same is also true of the rays which flow from B, or any other point, the representation IM will be nearer to the surface than the object; and because it is terminated by the perpendiculars AE and BF which incline to each other, as concuring at the centre, it will also appear less.

III. When an object is seen by reflection from a concave surface, the representation of it is various, both with regard to its magnitude and situation, according as the distance of the object from the reflecting surface is greater or less.

1. When the object is nearer to the surface than its focus of parallel rays, the image falls on the opposite side of the surface, is more distant from it, and larger than the object.

Thus, let AB (fig. 13.) be the object, SV the reflecting surface, F the focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the line CE, CR, which will be perpendicular to the surface; and let the rays AR, AG, be incident upon such points of it that they shall be reflected into an eye at H. Now, because the radiant points A and B are nearer the surface than F the focus of parallel rays, the reflected rays will diverge, and will therefore proceed as from some points on the opposite side the surface; which points, by the observation laid down at the beginning of this section, will be in the perpendiculars AE, BR, produced, suppose in I and M: but they will diverge in a less degree than their incident ones (see the proposition just referred to), and therefore the said points will be farther from the surface than the points A and B. The image therefore will be on the opposite side of the surface with respect to the object; it will be more distant than it; and consequently, being terminated by the perpendiculars CI and CM, it will also be larger.

Of Reflection.

2. When the object is placed in the focus of parallel rays, the reflected rays enter the eye parallel, in which case the image ought to appear at an infinite distance behind the reflecting surface; but the representation of it, for the like reasons that were given in the foregoing case, being large and distinct, we judge it not much farther from the surface than the image.

3. When the object is placed between the focus of parallel rays and the centre, the image falls on the opposite side the centre, is larger than the object, and in an inverted position.

Thus let AB (fig. 14.) represent the object, SV the reflecting surface, F its focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the lines CE and CN, which will be perpendicular to the surface; and let AR, AG, be a pencil of rays flowing from A. These rays proceeding from a point beyond the focus of parallel rays will after reflection converge towards some point on the opposite side the centre, which will fall upon the perpendicular EC produced, but at a greater distance from C than the radiant A from which they diverged. For the same reason, rays flowing from B will converge to a point in the perpendicular NC produced, which shall be farther from C than the point B; from whence it is evident, that the image IM is larger than the object AB, that it falls on the contrary side the centre, and that their positions are inverted with respect to each other.

4. If the object be placed beyond the centre of convexity, the image is then formed between the centre, and the focus of parallel rays is less than the object, and its position is inverted.

The proposition is the converse of the foregoing: for as in that case rays proceeding from A were reflected to I, and from B to M; so rays flowing from I and M will be reflected to A and B; if therefore an object be supposed to be situated beyond the centre in IM, the image of it will be formed in AB between that and the focus of parallel rays, will be less than the object, and inverted.

5. If the middle of the object be placed in the centre of convexity of the reflecting surface, the object and its image will be coincident; but the image will be inverted with respect to the object.

That the place of the image and the object should be the same in this case needs little explication; for the middle of the object being in the centre, rays flowing from thence will fall perpendicularly upon the surface, and therefore necessarily return thither again; so that the middle of the image will be coincident with the

Of Reflection.

the middle of the object. But that the image should be inverted is perhaps not so clear. To explain this, let AB (fig. 15.) be the object, having its middle point C in the centre of the reflecting surface SV; through the centre and the point R draw the line CR, which will be perpendicular to the reflecting surface; join the points AR and BR, and let AR represent a ray flowing from A; this will be reflected into RB: for C being the middle point between A and B, the angles ARC and CRB are equal; and a ray from B will likewise be reflected to A; and therefore the position of the image will be inverted with respect to that of the object.

In this proposition it is to be supposed that the object AB is so situated with respect to the reflecting surface, that the angle ACR may be right; for otherwise the angles ARC and BRC will not be equal, and part of the image will therefore fall upon the object and part off.

6. If in any of the three last cases, in each of which the image is formed on the same side the reflecting surface with the object, the eye be situated farther from the surface than the place where the image falls, the rays of each pencil, crossing each other in the several points of the image, will enter the eye as from a real object situated there; so that the image will appear pendulous in the air between the eye and the reflecting surface, and in the position wherein it is formed, viz. inverted with respect to the object in the same manner that an image formed by refracted light appears to an eye placed beyond it; which was fully explained under Prop. IV. (p. 5543.) and therefore needs not be repeated here.

But as to what relates to the appearance of the object when the eye is placed nearer to the surface than the image, that was not there fully inquired into. That point shall therefore now be more strictly examined under the following case, which equally relates to refracted and reflected light.

7. If the eye be situated between the reflecting surface and the place of the image, the object is then seen beyond the surface; and the farther the eye recedes from the surface towards the place of the image, the more confused, larger, and nearer the object appears.

Plate CCXII.

To explain this, let AB (fig. 16.) represent the object; IM its image, one of whose points M is formed by the concurrence of the reflected rays DM, EM, &c. which before reflection came from B; the other, I, by the concurrence of DI, EI, &c. which came from A: and let ab be the pupil of an eye, situated between the surface DP and the image. This pupil will admit the rays Ha, Kb; which, because they are tending towards I, are such as came from A, and therefore the point A will appear diffused over the space RS. In like manner the pupil will also receive into it the reflected rays Ka and Lb, which, because they are tending towards M, by supposition came from B; and therefore the point B will be seen spread as it were over the space TV, and the object will seem to fill the space RV; but the representation of it will be confused, because the intermediate points of the object being equally enlarged in appearance, there will not be room for them between the points S and T, but they will coincide in part one with another: for instance, the appearance of that point in the object, whose representation falls upon c in the image, will fill the space mn; and so of the rest. Now if the same pupil be removed into the situation ef, the reflected rays Ee and Gf will then enter the eye, and therefore one extremity of the object will appear to cover the space XY; and because the rays Of and Le will also enter it in their progress towards M, the point B, from whence they came, will appear to cover ZV; the object therefore will appear larger and more confused than before. And when the eye recedes quite to the image, it sees but one single point of the object, and that appears diffused all over the reflecting surface: for instance, if the eye recedes to the point M, then rays flowing from the point B enter it upon whatever part of the surface they fall; and so for the rest. The object also appears nearer to the surface, the farther the eye recedes from it towards the place of the image; probably because, as the appearance of the object becomes more and more confused, its place is not so easily distinguished from that of the reflecting surface itself, till at last when it is quite confused (as it is when the eye is arrived at M) they both appear as one, the surface assuming the colour of the object.

As to the precise apparent magnitude of an object seen after this manner, it is such that the angle it appears under shall be equal to that which the image of the same object would appear under were we to suppose it seen from the same place: that is, the apparent object (for such we must call it to distinguish it from the image of the same object) and the image subtend equal angles at the eye.

Dem. Here we must suppose the pupil of the eye to be a point only, because the magnitude of that causes small alteration in the apparent magnitude of the object; as we shall see by and by. Let then the point a represent the pupil, then will the extreme rays that can enter it be Ha and Ka; the object therefore will appear under the angle HaK, which is equal to its vertical one MaI, under which the image IM would appear were it to be seen from a. Again, if the eye be placed in f, the object appears under the angle GfO equal to IfM, which the image subtends at the same place, and therefore the apparent object and image of it subtend equal angles at the eye. *Q. E. D.*

Now if we suppose the pupil to have any sensible magnitude, such, suppose, that its diameter may be ab; then the object seen by the eye in that situation will appear under the angle HxL, which is larger than the angle HaK, under which it appeared before; because the angle at x is nearer than the angle at a, to the line IM, which is a subtense common to them both.

From this proposition it follows, that, were the eye close to the surface at K, the real and apparent object would be seen under equal angles (for the real object appears from that place under the same angle that the image does, as will be shewn at the end of this section): therefore, when the eye is nearer to the image than that point, the image will subtend a larger angle at it than the object does; and consequently, since the image and apparent object subtend equal angles at the eye, the apparent object must necessarily be seen under a larger angle than the object itself, where-

Of Reflection.

wherever the eye be placed, between the furface and the image.

As each point in the reprefentation of an object made by reflection is fituated fomewhere in a right line that paffes through its correfpondent point in the object, and is perpendicular to the reflecting furface, as was fhewn in the beginning of this fection; we may from hence deduce a moft eafy and expeditious method of determining both the magnitude and fituation of the image in all cafes whatever. Thus,

Plate CCXII.

Through the extremities of the object AB and the centre C, (fig. 17, 18, or 19.) draw the lines AC BC, and produce them as the cafe requires; thefe lines will be perpendicular to the reflecting furface, and therefore the extremities of the image will fall upon them. Through F the middle point of the object and the centre, draw the line FC, and produce it till it paffes through the reflecting furface; this will alfo be perpendicular to the furface. Through G, the point where this line cuts the furface, draw the lines AG and BG, and produce them this way or that, till they crofs the former perpendiculars; and where they crofs, there I and M the extremities of the image will fall. For fuppofing AG to be a ray proceeding from the point A and falling upon G, it will be reflected to B; becaufe FA is equal to FB, and FG is perpendicular to the reflecting furface; and therefore the reprefention of the point A will be in BG produced as well as in AC; confequently it will fall on the point I, where they crofs each other. Likewife the ray BG will for the fame reafon be reflected to A; and therefore the reprefentation of the point B will be in AG produced as well as in fome part of BC, that is, in M where they crofs. From whence the propofition is clear.

If it happens that the lines will not crofs which way foever they are produced, as in fig. 20. then is the object in the focus of parallel rays of that furface, and has no image formed in any place whatever. For in this cafe the rays AH, AG, flowing from the point A, become parallel after reflection in the lines HC, GB, and therefore do not flow as to or from any point: in like manner, rays flowing from B are reflected into the parallel lines KB and GA; fo that no reprefentation can be formed by fuch reflection.

From hence we learn another circumftance relating to the magnitude of the image made by reflection; viz. that it fubtends the fame angle at the vertex of the reflecting furface that the object does. This appears by infpection of the 17th, 18th, or 19th figure, in each of which the angle IGM, which the image fubtends at G the vertex of the reflecting furface, is equal to the angle AGB, which the object fubtends at the fame place; for in the two firft of thofe figures they are vertical, in the third they are the fame. And,

Farther, the angle ICM, which the image fubtends at the centre, is alfo equal to the angle ACB which the object fubtends at the fame place; for in the two firft figures they are the fame, in the laft they are vertical to each other.

From whence it is evident, that the object and its image are to each other in diameter, either as their refpective diftances from the vertex of the reflecting furface, or as their diftances from the centre of the fame.

IV. As objects are multiplied by being feen thro' tranfparent media, whofe furfaces are properly difpofed, fo they may alfo by reflecting furfaces. Thus,

Different Refrangibility of Light.

1. If two reflecting furfaces be difpofed at right angles, as the furfaces AB, BC, (fig. 21.), an object at D may be feen by an eye at E, after one reflection at F, in the line EF produced; after two reflections, the firft at G, the fecond at H, in the line EH produced; and alfo, after one reflection made at A, in the line EA produced.

2. If the furfaces be parallel, as AB, CD, (fig. 22.), and the object be placed at E and the eye at F, the object will appear multiplied an infinite number of times: thus, it may be feen in the line FG produced, after one reflection at G; in the line FH produced, after two reflections, the firft at I, the fecond at H; and alfo in FP produced, after feveral fucceffive reflections of the ray EL, at the points L, M, N, O, and P: and fo on *in infinitum*. But the greater the number of reflections are, the weaker the reprefentation will be.

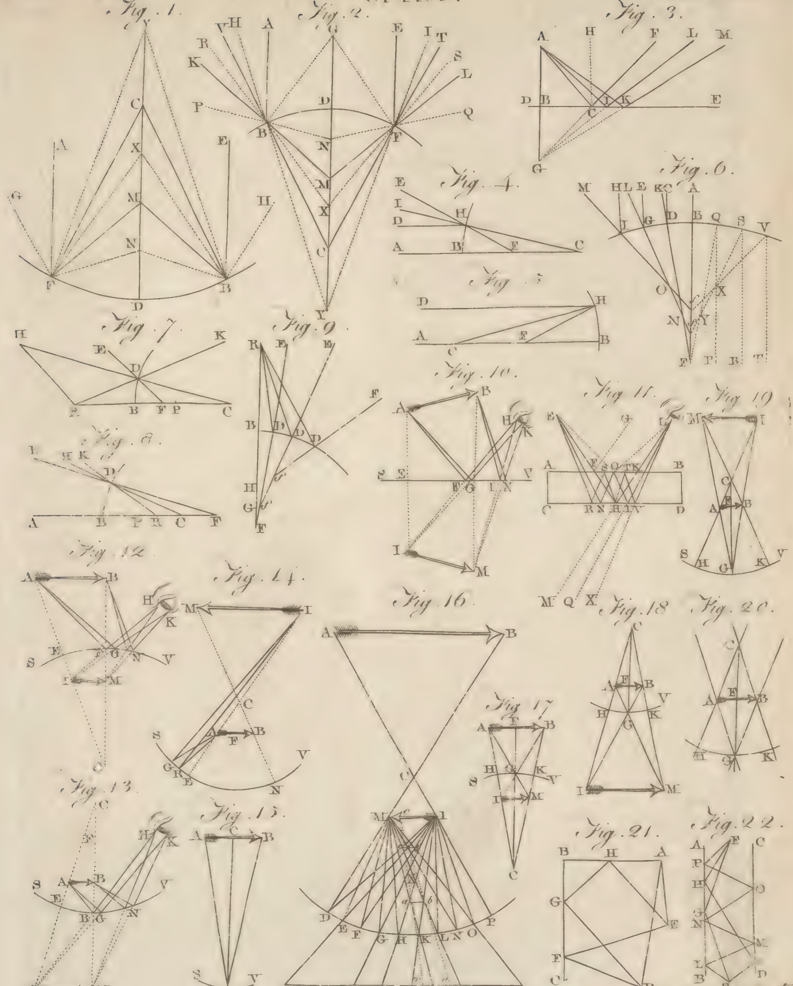
Sect. IV. *Of the different Refrangibility of Light.*

As this property of light folves a great number of the phenomena which could not be underftood by former opticians, we fhall give an account of it in the words of Sir Ifaac Newton, who firft difcovered it; efpecially as his account is much more full, clear, and perfpicuous, than thofe of fucceeding writers.

Plate CCXI. fig. 9.

"In a very dark chamber, at a round hole F, about one third of an inch broad, made in the fhut of a window, I placed a glafs prifm ABC, whereby the beam of the fun's light, SF, which came in at that hole, might be refracted upwards, toward the oppofite wall of the chamber, and there form a coloured image of the fun, reprefented at PT. The axis of the prifm, (that is, the line paffing thro' the middle of the prifm, from one end of it to the other end, parallel to the edge of the refracting angle) was in this and the following experiments perpendicular to the incident rays. About this axis I turned the prifm flowly, and faw the refracted light on the wall, or coloured image of the fun, firft to defcend, and then to afcend. Between the defcent and afcent when the image feemed ftationary, I ftopped the prifm and fixed it in that pofture.

"Then I let the refracted light fall perpedicularly upon a fheet of white paper, MN, placed at the oppofite wall of the chamber, and obferved the figure and dimenfions of the folar image, PT, formed on the paper by that light. This image was oblong and not oval, but terminated by two rectilinear and parallel fides and two femicircular ends. On its fides it was bounded pretty diftinctly; but on its ends very confufedly and indiftinctly, the light there decaying and vanifhing by degrees. At the diftance of $18\frac{1}{2}$ feet from the prifm the breadth of the image was about $2\frac{1}{8}$ inches, but its length was about $10\frac{1}{4}$ inches, and the length of its rectilinear fides about eight inches; and ACB, the refracting angle of the prifm, whereby fo great a length was made, was 64 degrees. With a lefs angle the length of the image was lefs, the breadth remaining the fame. It is farther to be obferved, that the rays went on in ftraight lines from the prifm to the image, and



A Bell Sculp.t

Different Refrangibility of Light.

and therefore at their going out of the prism had all that inclination to one another from which the length of the image proceeded. This image PT was coloured, and the more eminent colours lay in this order from the bottom at T to the top at P; red, orange, yellow, green, blue, indigo, violet; together with all their intermediate degrees in a continual succession perpetually varying."

Our author concludes from this experiment, and many more to be mentioned hereafter, "that the light of the sun consists of a mixture of several sorts of coloured rays, some of which at equal incidences are more refracted than others, and therefore are called *more refrangible.* The red at T, being nearest to the place Y, where the rays of the sun would go directly if the prism was taken away, is the least refracted of all the rays; and the orange, yellow, green, blue, indigo, and violet, are continually more and more refracted, as they are more and more diverted from the course of the direct light. For by mathematical reasoning he has proved, that when the prism is fixed in the posture above-mentioned, so that the place of the image shall be the lowest possible, or at the limit between its descent and ascent, the figure of the image ought then to be round like the spot at Y, if all the rays that tended to it were equally refracted. Therefore, seeing by experience it is found that this image is not round, but about five times longer than broad, it follows that all the rays are not equally refracted. And this conclusion is farther confirmed by the following experiments.

Plate CCXI. fig. 10.

"In the sun-beam SF, which was propagated into the room thro' the hole in the window-shut EG, at the distance of some feet from the hole, I held the prism ABC in such a posture, that its axis might be perpendicular to that beam: then I looked thro' the prism upon the hole F, and turning the prism to and fro about its axis to make the image *pt* of the hole ascend and descend, when between its two contrary motions it seemed stationary, I stopped the prism; in this situation of the prism, viewing through it the said hole F, I observed the length of its refracted image *pt* to be many times greater than its breadth; and that the most refracted part thereof appeared violet at *p*; the least refracted red, at *t*; and the middle parts indigo, blue, green, yellow, and orange, in order. The same thing happened when I removed the prism out of the sun's light, and looked through it upon the hole shining by the light of the clouds beyond it. And yet if the refractions of all the rays were equal according to one certain proportion of the sines of incidence and refraction, as is vulgarly supposed, the refracted image ought to have appeared round, by the mathematical demonstration above-mentioned. So then by these two experiments it appears, that in equal incidences there is a considerable inequality of refractions."

For the discovery of this fundamental property of light, which has opened the whole mystery of colours, we see our author was not only beholden to the experiments themselves, which many others had made before him, but also to his skill in geometry; which was absolutely necessary to determine what the figure of the refracted image ought to be upon the old principle of an equal refraction of all the rays: but having thus made the discovery, he contrived the following experiment to prove it at sight.

Different Refrangibility of Light.

"In the middle of two thin boards, DE, *de*, I made a round hole in each, at G and *g*, a third part of an inch in diameter; and in the window-shut a much larger hole being made, at F, to let into my darkened chamber a large beam of the sun's light, I placed a prism, ABC, behind the shut in that beam, to refract it towards the opposite wall; and close behind this prism I fixed one of the boards DE, in such a manner that the middle of the refracted light might pass through the hole made in it at G, and the rest be intercepted by the board. Then at the distance of about 12 feet from the first board, I fixed the other board, *de*, in such manner that the middle of the refracted light, which came through the hole in the first board, and fell upon the opposite wall, might pass through the hole *g* in this other board *de*, and the rest being intercepted by the board, might paint upon it the coloured spectrum of the sun. And close behind this board I fixed another prism *abc*, to refract the light which came through the hole *g*. Then I returned speedily to the first prism ABC, and by turning it slowly to and fro about its axis, I caused the image which fell upon the second board *de*, to move up and down upon that board, that all its parts might pass successively through the hole in that board, and fall upon the prism behind it. And in the mean time I noted the places, *M*, *N*, on the opposite wall, to which that light after its refraction in the second prism did pass; and by the difference of the places at *M* and *N*, I found that the light, which being most refracted in the first prism ABC, did go to the blue end of the image, was again more refracted by the second prism *abc*, than the light which went to the red end of that image. For when the lower part of the light which fell upon the second board *de*, was cast through the hole *g*, it went to a lower place M on the wall; and when the higher part of that light was cast through the same hole *g*, it went to a higher place, N, on the wall; and when any intermediate part of the light was cast through that hole, it went to some place in the wall between M and N. The unchanged position of the holes in the boards made the incidence of the rays upon the second prism to be the same in all cases. And yet in that common incidence some of the rays were more refracted and others less: and those were more refracted in this prism, which by a greater refraction in the first prism were more turned out of their way; and therefore, for their constancy of being more refracted, are deservedly called *more refrangible.*"

Plate CCXI. fig. 11.

Our author shews also, by experiments made with a convex glass, that lights (reflected from natural bodies) which differ in colour, differ also in degrees of refrangibility: and that they differ in the same manner as the rays of the sun do.

"The sun's light consists of rays differing in reflexibility, and those rays are more reflexible than others which are more refrangible. A prism, ABC, whose two angles, at its base BC, were equal to one another and half right ones, and the third at A a right one, I placed in a beam FM of the sun's light, let into a dark chamber through a hole F one third part of an inch broad. And turning the prism slowly about its axis until the light which went through one of its angles

Fig. 12.

Different Refrangibility of Light.

angles ACB, and was refracted by it to G and H, began to be reflected into the line MN by its base BC, at which till then it went out of the glass; I observed that those rays, as MH, which had suffered the greatest refraction, were sooner reflected than the rest. To make it evident that the rays which vanished at H were reflected into the beam MN, I made this beam pass thro' another prism VXY, and being refracted by it to fall afterwards upon a sheet of white paper *pt* placed at some distance behind it, and there by that refraction to paint the usual colours at *pt*. Then causing the first prism to be turned about its axis according to the order of the letters ABC, I observed, that when those rays MH, which in this prism had suffered the greatest refraction, and appeared blue and violet, began to be totally reflected, the blue and violet light on the paper which was most refracted in the second prism received a sensible increase at *p*, above that of the red and yellow at *t*: and afterwards, when the rest of the light, which was green, yellow, and red, began to be totally reflected and vanished at G, the light of those colours at *t*, on the paper *pt*, received as great an increase as the violet and blue had received before. Which puts it past dispute, that those rays became first of all totally reflected at the base BC, which before at equal incidences with the rest upon the base BC had suffered the greatest refraction. I do not here take notice of any refractions made in the sides AC, AB, of the first prism, because the light enters almost perpendicularly at the first side, and goes out almost perpendicularly at the second; and therefore suffers none, or so little, that the angles of incidence at the base BC are not sensibly altered by it; especially if the angles of the prism at the base BC be each about 40 degrees. For the rays FM begin to be totally reflected when the angle CMF is about 50 degrees, and therefore they will then make a right angle of 90 degrees with AC.

" It appears also from experiments, that the beam of light MN, reflected by the base of the prism, being augmented first by the more refrangible rays and afterwards by the less refrangible, is composed of rays differently refrangible.

" The light whose rays are all alike refrangible, I call *simple homogeneal* and *similar;* and that whose rays are some more refrangible than others, I call *compound heterogeneal* and *dissimilar*. The former light I call *homogeneal*, not because I would affirm it so in all respects; but because the rays which agree in refrangibility agree at least in all their other properties which I consider in the following discourse.

" The colours of homogeneal lights I call *primary, homogeneal* and *simple;* and those of heterogeneal lights, *heterogeneal* and *compound*. For these are always compounded of homogeneal lights, as will appear in the following discourse.

" The homogeneal light and rays which appear red, or rather make objects appear so, I call *rubrific* or *red making;* those which make objects appear yellow, green, blue, and violet, I call *yellow-making, green-making, blue-making, violet-making;* and so the rest. And if at any time I speak of light and rays as coloured or endowed with colours, I would be understood to speak not philosophically and properly, but grosly, and according to such conceptions as vulgar people in seeing all these experiments would be apt to frame. For the rays, to speak properly, are not coloured. In them there is nothing else than a certain power and disposition to stir up a sensation of this or that colour. For as sound in a bell or musical string or other sounding body, is nothing but a trembling motion, and in the air nothing but that motion propagated from the object, and in the sensorium it is a sense of that motion under the form of sound; so colours in the object are nothing but a disposition to reflect this or that sort of rays more copiously than the rest: in rays they are nothing but their dispositions to propagate this or that motion into the sensorium; and in the sensorium they are sensations of those motions under the forms of colours.

" By the mathematical proposition above-mentioned, it is certain that the rays which are equally refrangible do fall upon a circle answering to the sun's apparent disk, which will also be proved by experiment by and by. Now let AG represent the circle which all the most refrangible rays, propagated from the whole disk of the sun, would illuminate and paint upon the opposite wall if they were alone; EL the circle, which all the least refrangible rays would in like manner illuminate if they were alone; BH, CI, DK, the circles which so many intermediate sorts would paint upon the wall, if they were singly propagated from the sun in successive order, the rest being intercepted; and conceive that there are other circles without number, which innumerable other intermediate sorts of rays would successively paint upon the wall, if the sun should successively emit every sort apart. And seeing the sun emits all these sorts at once, they must all together illuminate and paint innumerable equal circles; of all which, being according to their degrees of refrangibility placed in order in a continual series, that oblong spectrum PT is composed, which was described in the first experiment.

Plate CCXI. fig. 13.

" Now if these circles, whilst their centres keep their distances and positions, could be made less in diameter, their interfering one with another, and consequently the mixture of the heterogeneous rays, would be proportionably diminished. Let the circles AG, BH, CI, &c. remain as before; and let *ag, bh, ci,* &c. be so many less circles lying in a like continual series, between two parallel right lines *ae* and *gl*, with the same distances between their centres, and illuminated with the same sorts of rays: that is, the circle *ag* with the same sort by which the corresponding circle AG was illuminated; and the rest of the circles *bh, ci, dk, el* respectively with the same sorts of rays by which the corresponding circles BH, CI, DK, EL, were illuminated. In the figure PT composed of the great circles, three of those, AG, BH, CI, are so expanded into each other, that three sorts of rays, by which those circles are illuminated, together with innumerable other sorts of intermediate rays, are mixed at QR in the middle of the circle BH. And the like mixture happens throughout almost the whole length of the figure PT. But in the figure *pt*, composed of the less circles, the three less circles *ag, bh, ci,* which answer to those three greater, do not extend into one another; nor are there any where mingled so much as any two of the three sorts of rays by which those circles are illuminated, and which in the figure PT are all of them intermingled at QR. So then, if we would diminish the mixture

Different Refrangibility of Light.

mixture of the rays, we are to diminiſh the diameters of the circles. Now theſe would be diminiſhed if the ſun's diameter, to which they anſwer, could be made leſs than it is, or (which comes to the ſame purpoſe) if without doors, at a great diſtance from the priſm towards the ſun, ſome opaque body were placed with a round hole in the middle of it to intercept all the ſun's light, except ſo much as coming from the middle of his body could paſs through that hole to the priſm. For ſo the circles AG, BH, and the reſt, would not any longer anſwer to the whole diſk of the ſun, but only to that part of it which could be ſeen from the priſm through that hole; that is, to the apparent magnitude of that hole viewed from the priſm. But that theſe circles may anſwer more diſtinctly to that hole, a lens is to be placed by the priſm to caſt the image of the hole (that is, every one of the circles AG, BH, &c.) diſtinctly upon the paper at PT; after ſuch a manner, as by a lens placed at a window the pictures of objects abroad are caſt diſtinctly upon a paper within the room. If this be done, it will not be neceſſary to place that hole very far off, no not beyond the window. And therefore, inſtead of that hole, I uſed the hole in the window-ſhut as follows.

Plate CCXI. fig. 14.

"In the ſun's light let into my darkened chamber through a ſmall round hole in my window-ſhut, at about 10 or 12 feet from the window, I placed a lens MN, by which the image of the hole F might be diſtinctly caſt upon a ſheet of white paper placed at I. Then immediately after the lens I placed a priſm ABC, by which the trajected light might be refracted either upwards or ſideways, and thereby the round image which the lens alone did caſt upon the paper at I, might be drawn out into a long one with parallel ſides, as repreſented at *pt*. This oblong image I let fall upon another paper at about the ſame diſtance from the priſm as the image at I, moving the paper either towards the priſm or from it, until I found the juſt diſtance where the rectilinear ſides of the image *pt* become moſt diſtinct. For in this caſe the circular images of the hole, which compoſe that image, after the manner that the circles *ag*, *bh*, *ci*, &c. do the figure *pt*, were terminated moſt diſtinctly, and therefore extended into one another the leaſt that they could, and by conſequence the mixture of the heterogeneous rays was now the leaſt of all. The cirlces *ag*, *bh*, *ci*, &c. which compoſe the image *pt*, are each equal to the circle at I; and therefore, by diminiſhing the hole F, or by removing the lens farther from it, may be diminiſhed at pleaſure, whilſt their centres keep the ſame diſtances from each other. Thus, by diminiſhing the breadth of the image *pt*, the circles of heterogeneal rays that compoſe it may be ſeparated from each other as much as you pleaſe. Yet inſtead of the circular hole F, it is better to ſubſtitute an oblong hole ſhaped like a parallelogram with its length parallel to the length of the priſm. For if this hole be an inch or two long, and but a 10th or 20th part of an inch broad, or narrower, the light of the image *pt* will be as ſimple as before, or ſimpler; and the image being much broader, is therefore fitter to have experiments tried in its light than before.

"Homogeneal light is refracted regularly without any dilatation, ſplitting, or ſhattering of the rays; and the confuſed viſion of objects ſeen through refracting bodies by heterogeneal light, ariſes from the different refrangibility of ſeveral ſorts of rays. This will appear by the experiments which will follow. In the middle of a black paper I made a round hole about a fifth or a ſixth part of an inch in diameter. Upon this paper I cauſed the ſpectrum of homogeneal light, deſcribed in the former article, ſo to fall that ſome part of the light might paſs through the hole in the paper. This tranſmitted part of the light I refracted with a priſm placed behind the paper; and, letting this refracted light fall perpendicularly upon a white paper, two or three feet diſtant from the priſm, I found that the ſpectrum formed on the paper by this light was not oblong, as when it is made in the firſt experiment, by refracting the ſun's compound light, but was, ſo far as I could judge by my eye, perfectly circular, the length being nowhere greater than the breadth; which ſhews that this light is refracted regularly without any dilatation of the rays, and is an ocular demonſtration of the mathematical propoſition mentioned above.

"In the homogeneal light I placed a paper circle of a quarter of an inch in diameter; and in the ſun's unrefracted, heterogeneal, white light, I placed another paper circle of the ſame bigneſs; and going from theſe papers to the diſtance of ſome feet, I viewed both circles through a priſm. The circle illuminated by the ſun's heterogeneal light appeared very oblong, as in the ſecond experiment, the length being many times greater than the breadth. But the other circle illuminated with homogeneal light appeared circular, and diſtinctly defined, as when it is viewed by the naked eye; which proves the whole propoſition mentioned in the beginning of this article.

"In the homogeneal light I placed flies and ſuch like minute objects, and viewing them through a priſm I ſaw their parts as diſtinctly defined as if I had viewed them with the naked eye. The ſame objects placed in the ſun's unrefracted heterogeneal light, which was white, I viewed alſo through a priſm, and ſaw them moſt confuſedly defined, ſo that I could not diſtinguiſh their ſmaller parts from one another. I placed alſo the letters of a ſmall print one while in the homogeneal light, and then in the heterogeneal; and viewing them through a priſm, they appeared in the latter caſe ſo confuſed and indiſtinct that I could not read them; but in the former, they appeared ſo diſtinct that I could read readily, and thought I ſaw them as diſtinct as when I viewed them with my naked eye; in both caſes, I viewed the ſame objects through the ſame priſm, at the ſame diſtance from me, and in the ſame ſituation. There was no difference but in the lights by which the objects were illuminated, and which in one caſe was ſimple, in the other compound; and therefore the diſtinct viſion in the former caſe, and confuſed in the latter, could ariſe from nothing elſe than from that difference in the lights. Which proves the whole propoſition.

"In theſe three experiments, it is farther very remarkable, that the colour of homogeneal light was never changed by the refraction. And as theſe colours were not changed by refractions, ſo neither were they by reflections. For all white, grey, red, yellow, green, blue, violet bodies, as paper, aſhes, red lead, orpiment, indigo, bice, gold, ſilver, copper, graſs, blue flowers, violets, bubbles of water tinged with various colours,

Different Refrangibility of Light.

colours, peacocks feathers, the tincture of lignum nephriticum, and such like, in red homogeneal light appeared totally red, in blue light totally blue, in green light totally green, and so of other colours. In the homogeneal light of any colour they all appeared totally of that same colour; with this only difference, that some of them reflected that light more strongly, others more faintly. I never yet found any body which by reflecting homogeneal light could sensibly change its colour.

"From all which it is manifest, that if the sun's light consisted of but one sort of rays, there would be but one colour in the world, nor would it be possible to produce any new colour by reflections and refractions, and by consequence, that the variety of colours depends upon the composition of light.

"The solar image *pt*, formed by the separated rays in the 5th experiment, did in the progress from its end *p*, on which the most refrangible rays fell, unto its end *t*, on which the least refrangible rays fell, appear tinged with this series of colours; violet, indigo, blue, green, yellow, orange, red, together with all their intermediate degrees in a continual succession perpetually varying; so that there appeared as many degrees of colours as there were sorts of rays differing in refrangibility. And since these colours could not be changed by refractions nor by reflections, it follows, that all homogeneal light has its proper colour answering to its degree of refrangibility.

"Every homogeneal ray considered apart is refracted, according to one and the same rule; so that its sine of incidence is to its sine of refraction in a given ratio: that is, every different coloured ray has a different ratio belonging to it. This our author has proved by experiment, and by other experiments has determined by what numbers those given ratios are expressed. For instance, if an heterogeneal white ray of the sun emerges out of glass into air; or, which is the same thing, if rays of all colours be supposed to succeed one another in the same line AC, and AD their common sine of incidence in glass be divided into 50 equal parts, then EF and GH, the sines of refraction into air, of the least and most refrangible rays, will be 77 and 78 such parts respectively. And since every colour has several degrees, the sines of refraction of all the degrees of red will have all intermediate degrees of magnitude from 77 to $77\frac{1}{8}$, of all the degrees of orange from $77\frac{1}{8}$ to $77\frac{1}{5}$, of yellow from $77\frac{1}{5}$ to $77\frac{1}{3}$, of green from $77\frac{1}{3}$ to $77\frac{1}{2}$, of blue from $77\frac{1}{2}$ to $77\frac{2}{3}$, of indigo from $77\frac{2}{3}$ to $77\frac{7}{9}$, and of violet from $77\frac{7}{9}$ to 78.
